It has been determined that the eyes of all persons under forty years of age must be measured for parallel light; that is to say, light emanating from an object placed at 20 feet, English measure, or 6 meters, French measure; and, that the relative acuity of visual perception is determined at the same time by securing objects of definite size, to be seen at an angle of 5 minutes, or any multiple of that angle up to 60 at that distance. No other distance, and no other size of test object may be substituted without destroying the value of the test. Excepting in such cases as the eye may not be able to see the largest of the test objects at six meters, then the greatest distance at which the No. 60 test object can be seen, with correcting glass, expresses the numerator of the fraction whose denominator is 60; as 3-60 would indicate three meters as the greatest distance at which that object is seen.

It will not do to have a shorter distance with a relatively smaller sized object, as the value of parallel rays of light is definite, and not comparative. With the adjusting power of the eye completely suspended, the lens required to develop normal acuity of visual perception, under these conditions, represents the exact amount of the error of refraction in that eye, and will be the lens which it is necessary for such an eye to wear in all cases of hypermetropia, or of plain astigmatism, for all distances.

It was formerly believed the hypermetropic eye required correction of near objects only. For persons making little use of the eyes for near vision, as for example, the common laborer, this may be true; but, for students and others given to habits of study, and for artisans engaged in constant work, it will soon be found a full correction is required. Many persons do not require accurate vision, and not being able to appreciate the nice distinction and refinement of clear vision in the details of small objects, may even be better satisfied with complete or imperfect correction of errors of refraction; so that the personal equation of each individual must be considered in determining the adjustment of glasses.

For the comfortable use of glasses, however, and to secure the best results, it is necessary the disc should be large enough to prevent its rim from obscuring the field of vision. It must be set in such a manner that the plane of its main surface shall lie at right angles to a line drawn from the eye to the object looked at, and the two glasses must be carefully adjusted with reference to the distance between the pupils of the eyes, so the two eyes may enjoy equal advantages in looking through the lenses. If the lenses be set high, and the eye be turned so that the general plane occupied by the lenses shall not be at right angles to the visual line, inharmonious muscular action will soon result in a sense of fatigue in the eyes, and the use of the glasses will be unsatisfactory. It is just as essential that the proper adjustment of the lens shall be secured, as that the proper lenses for the correction of refraction shall be determined.

Allowing that, in the choice of lenses, proper rules for the determination of their necessity have been observed, even the lenses with which the test had been made, may be defective in construction. Every case of test lenses as it comes from the manufacturer is found to contain from 10 to 20 per cent. of defective lenses, so it is necessary that even the test case itself should have every one of its lenses subjected to measurement by Snellen's phakometer, or some other phakometer which measures, not the curvature of the surface of the lens, but is refracting properties. The practitioner who prescribes glasses should al-

ways have his patient return with them for measurement, in order to see that no mistake has been made either in the grinding of the lenses, or their adjustment to the patient's eyes.

Many of those suffering from a variety of the neuroses, which harass and annoy the general practitioner of medicine, are subjects of errors of refraction. The neurologist will tell you some of his most obstinate cases are relieved by the aid of the ophthalmologist. In fact, the correction of errors of refraction in the eye relieves some forms of mania.

Most of the cases of muscular imbalance in the eyes are the result of wearing unsuitable or improperly adjusted glasses. Shall we wonder at this when we reflect that large numbers of people go to the jeweler's clerk to obtain their glasses; or, to one of those persons who calls himself an optician, whose office is upon some thoroughfare, in the department store, or at the entrance to the theatre, at the state fair, or in the public park. It should be known that spectacles are optical instruments, requiring great care in their selection, and most painstaking accuracy of adjustment, and that they are not to be worn by persons having certain diseases, either of constitutional or local origin, in the eyes.

Wearing glasses is quite a serious business, and should never be undertaken without competent medical advice. We often see a rheumatic person, poorly nourished, and harassed by the ordinary problems of life, going from one jeweler to another buying glasses, and in a few weeks this person is laid up with a visually fatal attack of glaucoma, or it may be a retinitis hemorrhagen. Persons with slight errors of refraction might get on comfortably enough until some constitutional debility renders muscular effort somewhat difficult. The patient may put on glasses, which apparently improve the sight, and go on with chronic nephritis until finally organic retinal changes forces the victim to consult a specialist, who may, too late, discover evidences of the advanced renal lesion. Ophthalmoscopic examination may disclose the first evidence of arterio-sclerosis, of intra-cranial disease, or of previously unsuspected syphilis. It has often happened in my experience to discover the presence of serious constitutional diseases in persons whose first ground of complaint was in relation to failing sight.

A large volume might be written on the subject of the choice of glasses, leaving out of consideration entirely the mathematical aspects of the question. It is my opinion every general practitioner of medicine should be able to make use of the ophthalmoscope for diagnostic purposes at least, and be able to know therefore, the difference between those symptoms of fatigue in the eye due to errors

of refraction, and organic changes of the retina in chronic nephritis, and other diseases presenting ocular symptoms.

Hypermetropic patients having full correction, may safely go on without change of glasses until past the age of forty, perhaps until forty-five years of age. At that time the emmetropic eye and the hypermetropic eye will exhibit evidences of presbyopia, when a change of glasses for near objects becomes necessary. In most persons of studious habits, or others making much use of the eyes for near vision, changes will now be required every two or three years until the age of fifty, or fifty-five, when the entire function of accommodation will usually be found to have ceased, thus terminating the ordinary course of change of refraction. The astigmatic eye of the hypermetropic type will likely need less frequent changing, because of the athletic accommodating power usually found in astigmatic eyes. In the myopic eye, where near objects may be seen at a distance of fifteen inches, no correction for near vision should be allowed, excepting alone in cases of myopic astigmatism. The subject of this defect of refraction may wear the same glasses for both far and near vision for an ordinary lifetime. There are, of course, many exceptions to this rule, but in a majority of cases it will hold good.

There are so many modifying conditions, and there is so much scientific detail involved in the determination of errors of refraction in the human eye, that no persons excepting a well-qualified physician should be intrusted with the performance of this important service to afflicted humanity.

DISCUSSION.

Adolph O. Pfingst: Dr. Reynolds' has given us a very learned paper on the history of glasses, something that I am free to confess I am not very familiar with. It is very interesting to learn how the wearing of glasses started and has progressed up to the present time. I agree thoroughly with Dr. Reynolds in what he says about the promiscuous fitting of glasses. It is not only the layman who goes to the optician or the druggist for his glasses, for I have known of doctors securing glasses at dry-goods stores, and at jewelry stores. This is harmful not so much because of the actual harm done by the glasses, but cause the patient is made to feel safe, and thereby loses valuable time before securing proper lenses.

The optician will tell the individual that it may take a year or more to get used to wearing the glasses, but that he must persist, and he will perhaps go along for two or three years when there is really some serious condition that is responsible for the impairment of vision, such as Bright's disease, etc.

Glass-wearers can be divided into several classes, one of which is composed of those individuals who wear glasses to bring about an improvement in vision, near-sighted and astigmatic persons, and these individuals wear their glasses at all times, for both distance and close work.

Another class is made up of individuals who must have glasses for muscle unbalance. Right here I would like to say that I believe a great deal of prejudice exists among the laity in regard to wearing glasses. It is not an uncommon thing for a mother to come to us and say—"Doctor, I have a child that is cross-eyed, but I do not want him to wear glasses, as he is too young." Others will say that they would rather have an operation and get through with it than to have the child wear glasses. The truth of it is, if we have an individual with a high degree of hypermetropia and squint, and operate during childhood, the time will come later in life when he must wear glasses for optical purposes, which may then cause a divergent squint, or a "cock-eye" in stead of a cross-eye. Many parents do not want their children to wear glasses, and this must be explained to them.

A third class is composed of those who wear glasses for therapeutic reasons, to relieve headache, or various reflex disorders. Hysterical individuals are frequently relieved of symptoms by wearing glasses, even though the error of refraction is very slight at times.

Another class is represented by the presbyope, or the individual who wears glasses because the elasticity of his lens will not allow it to accommodate at the ordinary reading distance.

Still another class is composed of those who wear glasses for show, as you know it is not uncommon in England and Germany, especially among the army officers, to see them with a monocle before one eye.

I want to say again that I have thoroughly enjoyed the doctor's paper and have gained a great deal of information.

M. L. Ravitch: I would like to call attention to one point that Dr. Reynolds missed. He mentioned the stomach man, the surgeon, and the neurologist, but he left out the dermatologist. It is a fact that a good many cases of alopecia areata, in which the parasitic type can be excluded, may be relieved by wearing glasses.

Last year I saw a lady, who is a school teacher, with two spots of alopecia areata over her temples. The condition resisted every form of treatment I could think of. Inasmuch as microscopic examination showed no parasites, I came to the conclusion that the trouble was of non-infective origin, and put her on tonics and what-not, but still the condition did not improve. Upon going carefully into her history I found that her eyes had been giving her some trouble and sent her to an ophthalmologist, who fitted her with glasses and, somewhat to my surprise, the hair began to come back in. I looked up the litera-

ture and found that a good many cases of this kind had been cited, and it seems that alopecia areata over the temples, where the parasitic type can be excluded, is very often due to defects of the eyes.

N. D. Abell: I think we have had a very brilliant paper and I have appreciated it very much, as well as the discussion. Some few points have been brought out with which I do not exactly agree. If I understood the essayist correctly, he said that cases of myopic astigmatism should use the same glasses for reading and distance all through life. I disagree with him here, because after they reach as much as 3 D., total presbyopia, it is necessary for the glasses to be changed, usually, for best results, and in progressive myopia.

Again, the essayist said, if I did not misunderstand him, that some persons go into stores and get glasses of different dimensions and, after wearing them for a while, their eyes cross, and they have more trouble. I am not in favor of promiscuously selecting glasses—I am opposed to it, as disense is often overlooked, but one question I would like to ask is, how is it that the glasses they get will cross the eyes? This is where I take issue. As a rule, the glasses they get are the same strength all around; they are always plus lenses, and I deny that they cross the eyes. I may have misunderstood the essayist and, if so, I would like to be set right upon this point.

Another question I would like to ask is, what percentage of operations for strabismus, or cross-eyes, are successful? Dr. Pfingst brought out the fact that quite a few of these cases will be relieved by wearing glasses, and I heartily agree with him that if the later methods of higher optics were used, nearly all could be straightened. I have taken cases that had been operated upon unsuccessfully, and when I got through with them their eyes were straight and O. K.

In regard to hysteria, I believe a great many of these cases will be helped by wearing glasses, as nearly all (98 per cent) need them and are hyperopic. I have heard reports of cases of bed-wetting in children being relieved in that way. I heard a physician here make that statement. He claims that correcting astigmatism will relieve them, and it seems reasonable to believe that removal of the eye strain may do it occasionally by lessening the nerve tension.

Dudley S. Reynolds, (Closing): I have been very much entertained by the discussion.

Dr. Pfingst asked me to interpret this prescription for bi-focal lenses for the benefit of Dr. Harris. For distance, Plus 0.50 cylindrical axis, 90 degrees; for reading, an addition of Plus 0.50s, making this combination, Plus 0.50, 90 degrees plus 0.50s.

I would suggest that Dr. Harris put himself to the trouble of looking up a little of the liter-

ature on the subject of errors of refraction in the eyes. I do not know of any better literature than is to be found in the sixth and seventh volumes of Osler's *System of Modern Medicine*, recently published.

In regard to Dr. Abell's disquisition, he is the only person present this evening that I have heard say anything about glasses producing squint, or crossing people's eyes. I said nothing about it, nor have I heard Dr. Pfingst or any one else say anything about it. Furthermore, I did not say that people with myopia might wear the same glasses for distance and reading. I said myopic astigmatism—not spherical myopia—and distinctly stated that cases of spherical myopia able to see distinctly at fifteen inches, should be allowed no correction at all for near vision. Of course, such people could not wear the same glasses for both far and near vision, without injury to the eyes.

Now, as to Dr. Bruner's position that he prescribes glasses for those who want them. I make it a serious matter whenever any one consults me with reference to the use of glasses. I take care to determine, certainly and without doubt, the exact state of refraction in each eye, and if I find that no glasses are necessary, I so explain to the patient, and make the patient understand it. I take particular care to explain that persons who do not need glasses will be very much annoyed and harassed if they attempt to use them. There are no sensible people in the world wearing glasses for purely cosmetic effects, or for any other purpose except to correct errors of refraction, perceptibly and practically improving the sharpness of sight and affording better use of the eyes.

As to whether I prescribe spectacle frames, or the pinch-nose forms, I think I said somewhere in my essay that each individual is a law unto himself. The personal equation of each individual should be taken into consideration. There are people like our illustrious and lamented friend and colleague, the late Dr. William Bailey, the bridge of whose nose was high and broad, and whose pyramidalis nasi were particularly well developed, behind which the pinch nose frame might rest with scarcely perceptible pressure, and for such persons the pinch-nose form is most eminently suited. However, for a man with receding facial angle, and a thin-skinned, bony nose like mine, with a very broad and thin pyramidalis nasi muscle, which spreads out so wide that it cannot be tucked up at the edges, the spectacle frame is the only thing that will remain *in situ*. I have tried the various forms of pinch-nose frames, even including that patented humbug called the "Shur-On," and they would remain until a little perspiration formed under the point of pressure, or until I laughed, and then all of a sudden they would drop, and of course I am unable to wear them.

As to curing people's stomachs, or appendicitis,

or any form of disease, by the use of glasses, it is unanswerable and absurd; but reflex disturbances of the general system, operating indirectly through the central nervous system from eye-strain, can be benefited by glasses. A few cases of acute mania, now and then, are relieved, or even chronic mania may be relieved by the use of glasses. This only goes to show that the mania was brought on by constant harassment of the mind due to attempts to see objects. Upon taking away the source of the annoyance, the brain will become quiet, the hyperemic state subsides, and consequently the mental aberration ceases.

Now, as to the method of selecting lenses, the idea of anybody, no matter how intelligent he may be, under forty years of age, being able to walk into an establishment and select, even with the most painstaking care in the world, a pair of glasses that will fully correct his error of refraction, is ridiculous. Not until the accommodation of the eye is suspended, and it is placed in a perfectly quiescent state, so that the refraction of the eye can no longer, by any involuntary action, undergo any change, can a test of its refracting power be made with accuracy and certainty.

Now, how do we know when we have suspended the adjusting power of the eye. We have this fixed law, and that is the reason why no distance other than 20 feet or 6 meters should be adopted in making the test, using parallel rays of light, and determining by changing the lenses, what the patient can see. The patient is asked what is the first letter in the first line of the test card, then the next letter; then the last letter in the next line, etc. If the patient is able to see what is called 6-6 or, in English measure, 20-20, we have another card with smaller type, and we ask the patient if he can see any letters in the first line; what is the first letter? The second one? Can you name the third? When he has named two or three letters in that line, which constitutes the crucial test, we obscure that eye, substitute the other one, and determine what it requires to enable him to do the same with the other eye.

All this painstaking work is necessary to insure against mistakes, and the slight errors of refraction are more prone to create reflex neuroses than the graver ones, because the latter are so distinctly apparent that the patient himself feels that he has to have help for his eyes, while, on the other hand, he does not realize that the drawing sensation in his head—that peculiar kind of ache which strikes him somewhere in the temples, or in the top of the head and feels like it is drawing down the back of his neck—is due to his eyes. He realizes that something is the matter but does not know what it is. On the other hand, if he is conscious of the fact that he does not see small objects, or minute objects distinctly, he knows, by comparison with the people with whom he associates, that something is wrong with his eyes.

In regard to the manufacture of lenses, I want to say that our manufacturing opticians in the United States, greatly excel, in point of skill, nicety of finish, and uniformity of results, those of any other nation. The English astronomers and mathematicians evolved the great principles of the science of making lenses, and their adaptation to the correction of errors of refraction. The common people of England took it up first and we copied after them, and very shortly the Germans took it up to such an extent that it is said that a great many people in Germany are wearing glasses they do not need. I am unwilling to believe that statement. I have seen so few people willing to wear glasses, even when they are necessary, that I am unwilling to believe that many persons who suffer so little would wear them at all. I can understand how the snob will stick a monocle on his eye for effect; he looks like a man of great distinction and learning, he fancies, and pretends to see what is invisible to ordinary persons.

I thank you for your indulgence.

CLINICAL CASES AND SPECIMENS

SUPRAPUBIC PROSTATECTOMY.

By G. A. HENDON, Louisville.

I want it distinctly understood that I disclaim any purpose of using this theme as the vehicle of an argument for or against the suprapubic route to the prostate. I am neither an advocate nor an adversary of the suprapubic operation. I think that all controversies involving supposed advantages of the perineal over the suprapubic operation or vice versa are vain and futile.

That each operation has its place in surgery definitely secured, and their application as remedial measures depends solely upon two things:

1st. The pathology. 2nd. The experience and personal prejudices of the operator. The major portion of my experience in prostatic work has been with the perineal route. And I believe I can execute the operation with greater facility through the perineum than otherwise.

It would indeed be well if the application of the method of operation could be made to conform entirely with the pathology of the case in hand. But it is impossible to exclude the experience of the surgeon as a determining factor in the choice of methods.

It becomes our duty, however, to eliminate prejudice and preconceived opinions absolutely from the consideration of a choice of methods. With the importance of that end in view I have been reluctantly forced to admit that certain cases of prostatic hypertrophy can be

far better managed by the suprapubic than by the perineal route.

The burden of discretion falls upon the selection of the *certain* cases, which fare better if operated upon in a specified way.

1st. The fact is generally admitted that prostates which sit high in the saddle and are distinguished by a relatively exaggerated hypertrophy of the median bar, offer superior opportunities to the suprapubic method.

2nd. Cases in which immediate operation is demanded on account of retention of urine.

3rd. Cases in which it is difficult or impossible to introduce a guide into the bladder.

4th. Cases characterized by excessive hemorrhage.

I think that in all other cases the method of operation might properly be left to the individual experience and natural inclination of the operator. In connection with suprapubic operation my experience has made clear to me the fact that elaborate apparatus for drainage is superfluous. The main achievement of drainage is the prevention of clot formation inside the bladder. The danger of such a contingency is quite obvious. Should a clot of considerable size become infected with saprophytic bacteria sapraemia would likely occur therefore, I repeat, the chief object of post-operative drainage is to prevent such a disaster.

And if it were possible to obtain perfect hemostasis after the operation, no drainage need be provided for except via naturalis.

I have never had the courage that some operators have had to close the bladder completely without extra provision for drainage.

My practice has been to pack the bed of the enucleated prostate with gauze, sew up the incision of the bladder, all except a space large enough for the gauze to come through and act as a drain. The gauze is made to serve the double purpose of hemostasis and drain.

It is allowed to remain from 24 to 48 hours when danger of hemorrhage is generally considered to have passed. I have discarded tubes altogether in my suprapubic work.

At the time of the operation we introduce, through the urethra, a soft rubber catheter which is fixed in the urethra by a method that we shall describe, and serves all the purposes of the usual more elaborate provision for drainage.

During the 24 hours succeeding the operation a pint or more of a saturated solution of boric acid is injected through the catheter with a piston syringe every two hours.

This procedure goes far toward prevention of clot formation and cleanses the bladder of stagnant hemorrhage and operative debris.

After the first 24 hours the washings are repeated about four times a day for the next

two days; after that twice and then once a day.

The catheter is removed at the end of the first week and the patient is usually able by that time to void voluntarily.

I consider this urethral route of drainage a distinct advance toward simplicity in the post-operative treatment and a decided gain for the patient's comfort. It might be that my experience in this regard is unique, but I confess I have never been able to obtain satisfaction to myself or comfort for my patient through a system of drainage based upon the principle of syphonage.

My main excuse for offering this paper is to bring to your attention the advantages of the urethra as a means of draining the bladder.

It is simple. It is direct. It is natural. Heretofore the main obstacle in the way of its employment has been the want of efficient means of retaining the catheter in position.

This obstacle I think I have overcome in the following way: I have no doubt many of you have employed the same or a similar device but a description is quite apropos.

A rubber tube one inch in diameter and four inches long is split to within one inch of its extremity and the bifurcations thus formed are attached along the upper and lower surfaces of the penis, with James faced adhesive plaster. A catheter is introduced into the urethra and pinned with a safety to the projecting nozzle of the larger tube. The end of the catheter is allowed to rest in a urinal or other suitable receptacle to collect the drainage.

I shall not tire you with a detailed report of cases but will summarize by saying that I have met with three in six months in which the suprapubic method seemed to be indicated and was employed with satisfactory results and the matter of drainage disposed of in the manner heretofore mentioned.

The first case was one in which the passage of hemorrhagic urine was the most conspicuous feature. Rectal examination did not disclose any considerable hypertrophy of the gland. Bladder irrigation was practiced twice daily for several days in the hope of clearing the urine.

There was ample clinical evidence of enlarged prostate. The irrigations failed utterly to achieve the object for which they were employed. Thinking that possibly there was a papilloma in addition to enlarged prostate we elected the suprapubic route as the one that would give us better opportunities to visualize the bladder cavity. The hemorrhage had been so profuse we could gain nothing by a cystoscopic examination.

The patient was placed on a table in the Trendelenburg position. The bladder opened and a large, soft, succulent, somewhat

pedunculated prostatic tumor was seen. Its surface was covered with soft thickened mucous membrane richly supplied with thin vessels that bled to the touch. The mucous membrane was divided, the prostate enucleated and the bladder cavity packed with gauze to control the hemorrhage.

The next case was one in which no enlargement could be felt per rectum but the patient had been complaining for a period of two years. The symptoms I interpreted as prostatic hypertrophy although he came with a diagnosis of deep urethral stricture.

We were able upon the day of his arrival to pass a metal catheter but subsequently we found it impossible to get an instrument of any kind into the bladder. He suffered with complete retention.

The case proved, at operation, to be one of prostatic hypertrophy with exaggerated enlargement of the median bar.

This unusual enlargement of the middle lobe arrested the passage of instruments and laid the foundation of diagnosis of stricture.

The third patient was operated on suprapubically because the enlarged gland seemed to grow in an upward direction and did not appear to encroach upon the rectal space.

We were able to cystoscope this case and visualize the median lobe projecting like a mountain peak in an upward direction closing almost entirely the visceral meatus of the urethra.

DISCUSSION.

C. B. Spalding: While my experience has been rather limited, I am inclined towards the suprapubic route for one reason especially. We know that the urinary outlet is controlled by two things, the prostate itself and the urogenital diaphragm. If we go below, we are bound to destroy the greater portion of the prostatic urethra, and we are very likely to destroy the urogenital diaphragm, while if we go above, we can protect the latter because the prostate is above that. That is the best reason I know of for going above. Another reason is that when the prostatic urethra is removed from below it leaves a sacculation, and a sacculated puddle of urine will form, keeping the sinus open. This will not occur if you go above, because that space is not connected with the outside wound.

In regard to washing out the ureter, I think the doctor was very fortunate. I have had to wash out these bladders frequently, and I have never seen a catheter as small as a No. 10 take care of it. As far as packing the space with gauze is concerned, that is all right, but where the destruction of the prostatic gland approaches the ureteral openings, you are going to pack the ureters and interfere with a free outflow.

The amount of hemorrhage that will ensue depends upon the condition of the prostate, and the

hemorrhage is sometimes profuse; the bladder fills up with blood clots and it is necessary to give the patient another anesthetic, open up and drain. I think we should have drainage through the urethra and one tube above also, in the suprapubic route, so that we can throw water into the bladder and wash the clots out. We may be successful with some of these cases where there is not much hemorrhage and the tumor pedunculated with packing and a small tube, but in a case where the entire prostatic urethra has to be removed, we are going to have a lot of hemorrhage, and I do not believe we can control it by packing alone, but must have free drainage, and continual irrigation.

F. T. Fort: I believe in having a large drainage tube in these bladders. Pryor's method, to my mind, is the best one that has been devised. He uses a very large drainage tube in the suprapubic wound and continues irrigation for several hours. This brings about haemostasis and at the same time washes out the clots.

I agree with Dr. Hendon that, in the majority of cases the suprapubic is the best route. I know it is the best route for a novice. I have done several operations by this route and they have all been successful. I was a little afraid of the perineal route, because I felt that it was more dangerous.

Jno. R. Wathen: A number of years ago we used to argue about which was the best method of doing hysterectomy, abdominal or vaginal, and I think the same principle applies as to which is the best route, above or below, in doing prostatectomy. I have done a good many prostatectomies both ways, and I am sure that there are distinct indications for either operation. Hugh Young's method is the ideal one in selected cases; in other cases we have to follow other methods.

Young's conservative perineal prostatectomy is certainly the ideal operation in selected cases. Where there is stricture associated with the prostatic condition, where the prostate is small and hard to get to, where we have little hidden pockets of fibrous and inflammatory material, I think the perineal route is much superior; but where we have a large, solid, adenomatous prostate, rising high into the bladder and in all probability twice as large as the cavity of the bladder itself, and if this is possibly associated with stone, as many of them are, then by all means go above. It does not matter how we drain, so long as we establish good free drainage.

J. Hunter Peak: I am like Dr. Wathen in regard to the route to be taken in doing a prostatectomy; it makes very little difference what route we use if the case is selected. Where the middle lobe of the prostate is involved and we have complete stoppage of urine from that cause, or where a catheter or drain cannot be inserted as a guide, as in Young's method, it is perhaps far the best to go above. It does not make much

difference which way we take, if the technique is carried out properly and the enucleation made complete, removing all the glandular tissue, (because if any of it remains it will grow again) and at the same time controlling the hemorrhage. As far as controlling the hemorrhage is concerned, I am sure that it can be controlled much easier and more safely through the perineal route. If you have done a suprapubic operation, you may have hemorrhage into the bladder, and if you have done a perineal operation and injured the bladder wall (which is often done) you will also have hemorrhage into the bladder. In either case the principal thing is to prevent the formation of blood clots, which can be done in this way: Before the patient leaves the operating room, fill up the bladder with several ounces of normal salt solution, and after he is put to bed, establish irrigation for a few hours, or until all evidence of hemorrhage has ceased. Should it start again, re-establish irrigation, which will prevent the formation of clots.

In regard to the use of boric acid solution, I do not think it is necessary, and I am quite sure that I will never use it again. I remember one case sent to me for operation, in which irrigation with boric acid solution had been carried out prior to operation, and at the time of operation a considerable quantity of a mealy substance was removed from the bladder, which, to my mind, had some connection with the boric acid irrigation. I do not believe it is wise to use it because it may be precipitated.

The cases reported by Dr. Hendon are unique and I think he selected the wisest method of operation in the cases he mentioned.

Hugh N. Leavell: I think Dr. Hendon got a very unusual result in the way of drainage with such a small catheter.

One danger that I think has been overlooked, particularly in connection with the perineal route, is that of getting into the rectum. I remember hearing Dr. Will Mayo say that an operator would get into the rectum twice in every twenty-five cases, and that he had had his two experiences of this kind in the first two cases, after which he did not use the perineal route any more, doing the others entirely by the suprapubic route. In my first case I was fortunate enough to get a nice hole into the rectum and it has not closed up yet. Fortunately, the man has a very good sphincter and can urinate and defecate through the same opening without any great degree of discomfort. Even with the conservative perineal prostatectomy advocated by Dr. Hugh Young, it is a very easy thing for a man who has not done several thousand prostatectomies to get into the rectum.

In regard to drainage, I do not believe that gauze, in the majority of instances, is sufficient to carry away the blood clots. Like Dr. Wathen, I prefer to have a good large tube in there.

I do not believe the use of boric acid is wise,

because some of it will be retained and may become a means of infection, or a nucleus for the formation of stone.

Irrigation, established at once and kept up continuously for 24 to 48 hours, or as long as the return shows any blood clots, is, I think, essential to success in the after treatment of suprapubic prostatectomy.

C. B. Spalding: I did not mean to make the statement that we should not at all times use our better judgment as to the best route to take; I merely said that the suprapubic route is the better one as a rule, and when in doubt go above. I believe there are indications for the other route, but the great objection to it is this: There is a great deal of difference in taking out a prostate gland and getting the patient home, and taking out a prostate gland and getting the patient well. I can point out some four or five cases in this State, that were operated upon by Dr. Young himself, who are to-day wearing urinals. That is, to a certain extent, a successful operation, but not as successful as it would have been had the patient's urinary control been preserved, and I believe there is a better chance for the patient to retain urinary control by the suprapubic than by the perineal route.

G. A. Hendon, (Closing): I did not mean to convey the idea that I believe the suprapubic route to be preferable to the perineal route. If any one had asked me the general question as to which was the best way to do a prostatectomy, I would unhesitatingly have said by the perineal route. I have done more that way and the results have been very satisfactory. What I tried to do in this report was to call your attention to those cases in which the suprapubic route is the preferable one. No one can say that either is better than the other as a general proposition; the method must be suited to the case in hand. Why do we drain the bladder? To get rid of the blood clots and to avoid sepsis. If you clean the bladder beforehand you are not running any danger of sepsis. If you do the operation properly you are not running any danger from hemorrhage. When I saw hemorrhage, I mean hemorrhage that will jeopardize the life, or affect the condition of the patient. It is the simplest thing in the world to make an opening in the mucous membrane of the prostate, on its upper border, and then, following the line of cleavage, pass the finger under the mucous membrane and proceed down over the prostate and then along each side. I have never had any trouble in finding that line and following it and emulating the prostate, unless it happens to be a malignant condition, in which event we can do no good anyhow. When the prostate is enucleated in this manner, the mucous membrane falls down into the bed of the prostate. The gauze is packed on top of the membrane and does not come in contact with the raw surfaces. Of course, there is going to be a certain degree of hemorrhage, but

irrigation every two hours the first twenty-four will keep the hemorrhage liquified and prevent the formation of clots, and as long as the blood is in a liquid state it will flow through a No. 10 catheter. Then the gauze is there to serve as a guide to the site of operation in the event of any emergency, so I do not see why anyone should dread hemorrhage under these circumstances.

Another point is this: I close the bladder right up to the point where the gauze comes through, with a catgut mattress suture. Then I close the abdominal incision with layers of catgut, and close the skin with horse-hair sutures. Now what is the advantage of this? Just as soon as the gauze is taken out the wound begins to heal, and ordinarily, at the end of a week or two weeks, it has absolutely healed, and you do not have one of these preambulating privies walking around. What you want to do is to put the patient back in as nearly as possible the same condition in which he was before he got sick, and if you close the wound with the object to promote healing, it will heal, the fistula will close promptly and the patient will go home voiding urine in a natural manner.

NEPHROLITHOTOMY.

(REPORT OF CASE.)

By H. H. GRANT, Louisville.

Patient, a male, 35 years of age, was sent to me with a diagnosis of appendicitis of two years standing. Upon examination I found that a good deal of his pain was referred to the region of the kidney and, although he was somewhat tender over the appendix, the pain was located in the region of the ureter rather than directly over the appendix. At any rate, the history of attacks of colic (presumably in the kidney,) and the fact that tenderness was marked over the right kidney, led me to advise an examination of the urine and an X-ray photograph. The urine, on two examinations, showed distinct evidence of blood. There was no evidence of kidney disease aside from the fact that the urine contained some albumin, probably due to the presence of blood. The X-ray picture, which was made by Dr. Bruce, disclosed the presence of two stones, which were believed to be located in the pelvis of the kidney. A control picture was made which confirms the diagnosis, and this in connection with the findings by other forms of investigation, led us to operate on the man. I had the valuable assistance of Dr. Sherrill at the operation. The operation was done in the usual manner, by an oblique incision, beginning at the margin of the ribs and carried downward and slightly outward so as to make a pretty large exposure. This patient was five feet seven inches in height and weighed 180 pounds; he was rather bulky

and had a good deal of fat. Some little difficulty was experienced in getting the kidney out where it could be easily handled. No stones could be felt in the kidney after it had been exposed and the capsule peeled away. With an assistant pressing upon each side of the kidney to control the hemorrhage, a free incision was made and we were able to remove these four stones, which are illustrative of how much material of a destructive character may be present in the kidney without any distinct indications of its presence. But for the findings upon X-ray examination, we might have hesitated to split open a kidney as sound as this one apparently was. The hemorrhage which followed the incision, while not dangerous, was sufficient to require packing which was introduced in such a way as to come between the kidney structure and the capsule, pushing the capsule down and making direct pressure. No sutures were introduced, as it was believed that the packing would be sufficient to hold the kidney together.

This man had rather a severe reaction, but made a satisfactory, though gradual, recovery, and at the end of ten days he was able to be up. A sinus remained however, and a fistulous tract, with the escape of more or less urine for about eight weeks. He went home at the end of three weeks and this sinus gradually closed up. Four weeks later he wrote me that the sinus had closed and he was completely restored to health. Three weeks afterwards, however, he telephoned me that he was in great pain and that he believed he had another stone in his kidney. He stated that there was considerable swelling and I advised him to have his physician open in the region of the sinus, which was done and a considerable amount of urine escaped. It contained no pus, but was simply urine that had become blocked up in there and formed a little puddle, causing the pain of which he complained. This occurred a second time, two weeks later, and this time he had it opened without communicating with me, and I learned of it subsequently. Within twelve weeks after the original operation the sinus had permanently closed. More than a year has now elapsed since the operation, and he has been perfectly free from pain or distress for at least nine months.

The interesting features in this case are: First, for two years this man was believed to have appendicitis and, although he was quite regularly under medical observation, correct diagnosis was not made until attention was directed to the kidney. Second, the fact that these four stones, which are sharp and jagged, remained in the kidney for a year or more (possibly two years) without producing any structural disease of the kidney, or, at least, not enough to produce pus or any pathological

condition that could be observed when the kidney was split open, except the trauma caused by their attempts to get through the ureter, which caused the pain.

DISCUSSION.

Jno. B. Wathen: I think Dr. Grant is to be congratulated upon his very early and accurate diagnosis in this case. Too often we make the mistake ascribing pain to some condition other than that which really exists, and probably operate for appendicitis or gall-stones, when in reality we are overlooking an early case of nephrolithiasis. The X-ray technique of to-day is so perfect and the danger so little, that in the hands of one familiar with the work diagnosis of such conditions as this is almost positive, and especially is this true in adult life, where we do not have to deal with pure uric acid stones. If we allow these cases to continue and make diagnosis only when the patient has a large pyonephrotic kidney, it is too late to get the best results from operation because the kidney is more or less completely destroyed, whereas, if we operate early, we can save the kidney.

In regard to the operative technique, there are one or two points upon which I would like to take issue with Dr. Grant.

In splitting the kidney, all hemorrhage can be avoided by opening, not through the kidney substance itself, but through the pelvis of the kidney, carefully suturing the hyperstructure and covering it with the little sheet of fat we find at this point. In this way we get complete closure and avoid a fistula. In suturing the kidney, I think we cannot do better than to follow the technique of Dr. Halsted, of the Johns Hopkins Hospital. He introduces a dull needle, or rather a probe, right across here (illustrated on blackboard), then brings the suture up and cut over the top of the kidney, allowing these sutures to remain on the outside of the capsule. It is a clumsy looking stitch, but it will absolutely prevent all hemorrhage. In this way the raw surfaces are brought together with strands of catgut, and the hemorrhage is absolutely checked.

Berger, of New York, has recently demonstrated a beautiful technique for the removal of stones lower down in the ureter, which are often associated with stones in the kidney. His technique for these deep stones, which we should never overlook, is to make an incision just as we do for an appendectomy, then go in and trace the ureter down over the rim of the pelvis to the bladder. If he finds a stone just in front of the opening into the bladder, he marks it and then, stripping the peritoneum back, goes down outside of the peritoneum removes the stone, and then closes up the peritoneum. It is a transperitoneal operation, and yet it is extraperitoneal.

In conclusion, I wish to heartily congratulate

Dr. Grant upon the fact that this sinus closed up, because it is the experience of most operators that these sinuses very rarely heal. Watson and Cunningham have devised a very ingenious arrangement by which the patient wears a tin can in the back, and they wear it for life, as a rule, unless the kidney is taken out.

H. H. Grant, (Closing): I think the incision made in this case is really the best for exploratory purposes. Where stones are present in the pelvis of the kidney they may be very easily reached by making an incision into the pelvis from below, but in many instances the stones are in the structure of the kidney itself and cannot be reached in this way. If the X-rays had shown this to be one large stone in the pelvis of the kidney, I would have sought it there, but even when we had the kidney out we could not feel it there, so I believed the wisest course was to make a free incision and expose the central portion of the kidney.

I believe that suturing in the manner suggested by Dr. Wathen would have been an advantage, because it would have helped to control the hemorrhage which was, in a degree, troublesome. While it was easily enough controlled by packing, still I would rather not have put packing in if it could have been avoided. Suturing was not done because we believed that packing would control the hemorrhage quicker than the other way.

As to the persistency of these sinuses, my knowledge of the literature and my own observation differ somewhat from those of Dr. Wathen. I think these sinuses nearly always close. Occasionally they do not, but in such cases it means that a stone has been left in the kidney. If the stones are all removed, these sinuses, like sinuses or fistulae elsewhere in the body when a foreign body is removed, will heal. In the majority of cases, except tuberculous conditions, these sinuses heal very promptly.

REPORT OF CASES.

By LOUIS FRANK, Louisville.

CASE I.—SARCOMA FOLLOWING TRAUMA.

I present this case merely to show the strength of the abdominal wall following excision of the fascia, and because of the fact that two years have elapsed since the operation for the removal of a sarcoma following trauma in this region.

In December, 1909, while playing, this child suffered a fall, striking her abdomen on a clock that was lying on the floor. Shortly afterwards a swelling was noted in the abdominal wall, but the skin overlying it was not discolored. At first it was tender to the touch. The tumor increased in size and then gradually became smaller. In the latter part of

January this patient was seen by Dr. Solomon, who later referred her to me. He had had some one else see her, and temporizing had been advised, which was followed, the child being put on syrup of iodid of iron, or something of that sort, in the meantime.

I saw the child in April, 1910, with the above history. The tumor had then begun to grow again, and was slowly increasing in size. It was not tender. The skin overlying it was not fixed to the growth, but the tumor itself seemed to be fixed in the tissues. I believed the child had a sarcoma, but did not want to commit myself until some of the tissue had been subjected to an examination. On April 21st, 1910, with this diagnosis, I made a two-inch incision over the tumor, in the line of the right rectus, below the umbilicus, and the growth, the size of a small egg, adherent to the right rectus, was removed. It was supplied by only one blood vessel. A suture was placed in this and the skin wound closed. The tumor was sent to Dr. Field, who made diagnosis of sarcoma, probably beginning in the fascia. This was communicated to the parents and a secondary operation advised. The reason wide incision was not made primarily was because I feared I would not be able to bring the fascia of the rectus together. On April 25th, four days later, a second operation was done under gas anesthesia, in this manner:

Taking the old seat of the growth as a central fixed point, a diamond-shaped area was marked off on the skin, the angles being about two inches from the central point, i. e., the distance between the opposite angles was about 4 inches. This incision was carried down through the fascia and a superficial portion of the muscle, enabling us to completely excise the seat of the original growth and its fascial attachment, as shown by microscopic examination. After splitting slightly the superior and inferior angles of the fascia, we were able, by this character of incision through the tissues, to approximate the edges of the fascia completely, notwithstanding the fact that, toward the mesial side, a portion of the fascia of the opposite rectus was cut away.

Union, with the aid of silk worm gut sutures, was by first intention, with only a small amount of deformity.

The child still has a slight deformity, but there is no weakness of the abdominal wall, and I do not believe there is much likelihood of a recurrence.

The subject of trauma as a cause of sarcoma or carcinoma is a very interesting one. It was gone into very thoroughly by Coley at the meeting of the Southern Surgical Society in Nashville last year.

CASE II.

About nine months ago I saw the brother of a young woman who is a nurse in this city, after his return from the West, with a fracture of the upper third of the thigh. He was progressing nicely and I was called to remove the dressing. I saw no more of him until the early part of last winter, when I was asked by Dr. Fleischaker and Dr. Tuley to see the man again. He had apparently recovered and was up walking about, when he had a recurrence of pain and discomfort at the site of the fracture at which point there gradually developed an enlargement. I made a diagnosis of sarcoma, and an X-ray picture was made by Dr. Bruce. At the time the patient came under Dr. Fleischaker's care the growth had attained extreme size and removal was out of the question. He died about six weeks ago. No autopsy was permitted, but I am satisfied he had a sarcoma arising at the point of fracture. He suffered a secondary spontaneous fracture before his death.

I do not recall having seen a case, aside from these two, in which sarcoma followed so rapidly after the injury, although we get an indefinite history of injury in a good many cases. I have seen cases of cancer of the breast where there was a history of an injury to the breast, but I have never seen any other cases with the relationship of injury as a cause so well-defined and clear-cut as in these two.

CASE I.—GASTROPTOSIS.

Mr. E. E. F., seen in October, with Dr. Buckner, of Shelbyville; had suffered much at the hands of many men for some time. He was a very neurotic individual, as most of these cases are. I was called to see him because the man was actually starving to death, and they desired to know if anything could be done for his relief in the way of opening his stomach and feeding him in that way. He was a typical gastropototic patient, with a very narrow waist compared to his size, and a very much diminished upper abdominal capacity. The measurements were not taken, but the history he gave was about as follows:

Chief complaint, loss of weight, weakness and starvation. Age 28; farmer; had always led a very regular life, devoid of dalliance with Venus or Bacchus. Mother and father living and well; also three brothers and a sister. Weight 152; height 6 feet 2 inches. About three years ago began to show digestive symptoms and feel weak; no vomiting. About a year ago began to lose weight and has lost probably thirty or forty pounds. Appetite very poor; bowels constipated during the past four years. Physical examination showed conditions which are probably best explained by the X-ray picture exhibited herewith.

The stomach was very markedly displaced downwards, the upper border being about 1 1-2 inches above the umbilicus and the lower border four inches below, or practically lying in the pelvis. The transverse colon was also lying in the pelvis. Above the umbilicus nothing could be felt. Both kidneys were mobile, but not to a very marked degree. This is very striking in a case with such marked gastropotosis and enteroposis. Furthermore, there was no descent of the liver. Blood count, 4,500,000. He had quite a good deal of food retention and suffered a great deal from this and from absorption of decomposed products.

I believed that the best thing to do for this man was to fasten up the stomach and do so as much as we could at one operation. He was brought here about the time of the meeting of the Mississippi Valley Medical Association in Nashville, and two gentlemen from England and one from New York, who were on their way to that meeting, saw him and were very much interested in the case.

The abdomen was opened and Bexes' operation done, consisting of plication of the gastro-hepatic omentum, the stomach in this way being lifted well up. One suture was also taken to fasten the stomach to the round ligament. The colon was then brought up and the gastro-colic omentum also plicated. Four or five layers of sutures were placed in the gastro-hepatic omentum and two layers in the gastro-colic omentum.

He was kept in bed for a month, but began to improve decidedly in four or five days. I have heard from him in the last two or three weeks. He has gained in flesh and weight, and is up and about, although he does not work about the farm and does not ride. He is now wearing an abdominal support. He eats well, has no gastric disturbance, and promises to be a cure.

CASE II.

I have here another plate of a patient seen the other day, who has indefinite symptoms and upon whom I shall operate to-morrow. The plate shows the colon lying in the pelvis.

CASE III.

We recently operated on another case, which is probably too early to report. This woman had decided prolapse of the stomach and transverse colon, and what I thought were two mobile kidneys, one a floating kidney. Upon operation, however, what I took to be a floating kidney proved to be a wandering spleen, with a pedicle sufficiently long to allow it to be lifted out of the abdominal incision. The stomach and colon were fixed by plication, using also the round ligament. At first, I thought I would take the spleen out, but upon making an upper incision and sus-

pending the stomach and colon, there was sufficient peritoneal structure around the vessels in the pedicle to lead me to believe that the spleen could be saved. Therefore, it was fixed to the margin of the rib by three 20-day catgut sutures. The operation was done too recently to make any definite report as to the ultimate outcome. Of course, the patient was told that this spleen might again come down and, if so, its removal would be the only thing to do. The removal of the spleen would have been the easiest procedure, and the reason I did not do it was because it might be of use to the individual at some time in the future.

DISCUSSION.

E. T. Bruce: Just a word in regard to the radiography carried out in these cases.

In each instance the patient was first given a bismuth meal, consisting of about four ounces of bismuth to a pint of milk. This was given fifteen minutes before the radiograph was made. The patient was then placed upon the table in a semi-reclining position, allowing the stomach to sag down to a greater extent than it would in a horizontal position, and the radiograph taken.

The first picture taken shows what Dr. Bell, of New York would term typical "fish-hook" stomach. The greater curvature of the stomach was down in the pelvis, while the pylorus was practically in normal position. The shadow to the left in the first picture is that of the colon distended with bismuth, given in an enema.

The second and third pictures show the large intestine filled with bismuth, given in an enema containing half a pound of bismuth and a quart of milk.

Wm. C. Dugan: The case of sarcoma of traumatic origin is certainly a very interesting one. I would like to add to the record two cases of sarcoma that were undoubtedly due to trauma. One of these was a man who was employed to install the seats in the large amphitheatre of the Louisville Medical College. He used his right leg to force the benches into place, and in doing so he injured the inner condyle. The injury gave him considerable trouble for a while, and after he thought he had recovered from it, he noticed an enlargement at the site of the injury. It continued to grow until finally it was excised, diagnosis of sarcoma made, and hip-joint amputation performed. Microscopical examination proved the tumor to be a sarcoma.

The second case was that of a somewhat younger man who was operated upon at the Gray Street Infirmary for a very large sarcoma of the lower part of the femur, due to an injury received while at work as a section hand on a railroad. A lever fell across his leg and came very near breaking it, and this tumor developed right at the site of the impact. The diagnosis of sarcoma was confirmed by microscopical examination.

I report these two cases as further evidence of the fact that sarcoma may be due to trauma.

Guy P. Grigsby: I would like to ask Dr. Frank if he ever used the Coley fluid in the treatment of sarcoma? It would appear that the case he reported would have been a typical one for the use of the Coley fluid and I presume that the results would have been very brilliant. I have treated ten or eleven such cases under the direction of Dr. Coley, but, unfortunately, all of these cases were practically hopeless at the time treatment was begun, and all of them speedily died. In only two cases that I recall did we get any improvement whatever.

Coley, I think, asserts that in all operable cases of sarcoma, the use of the fluid is best, and Dr. Frank's case would have been a splendid one upon which to try the treatment, and the result would have been flattering to Dr. Coley. Some of these cases treated with the Coley fluid as a post-operative measure will recover—just as in this case. I am trying to make clear that I do not believe the fluid has anything to do with the recovery of the patient; in other words, I do not place much faith in the value of this fluid from what I have seen of it. Dr. Coley is very enthusiastic about it, and, like other men who advocate any particular theory, he has probably been too much carried away by the apparent results.

J. Hunter Peak: Five or six years ago I reported to this society a number of cases of bone tumors, some of which were malignant and some were not. I remember reporting three that were malignant, two of which were due to injuries and one was not. All three of these cases were operated upon and only one is now living. The case in which the condition was not due to injury died in six or eight months from what was supposed to have been pulmonary tuberculosis. However, I did not believe that she died of tuberculosis. In another case, amputation was done at about the junction of the middle and lower thirds of the femur, and about a year later this patient developed general involvement of the glandular structures of the body and died. The third case was also operated upon and is still in perfect health, six or seven years having elapsed since the operation.

One of the cases operated upon and reported at the time mentioned, was of the shoulder blade. As far as I know that girl is still in perfect health.

There is no question that malignant conditions often follow trauma. We do not know the exact pathology of it, but we frequently see malignant conditions developing at the site of old fractures, and not only malignant conditions, but other bone tumors. I agree with Dr. Frank that in nearly every case of malignant disease, there will be found a more or less definite history of traumatism.

Ellis S. Allen: I think Dr. Frank is especial-

ly to be congratulated upon the strong abdominal wall that this little girl has following operation. I am not at all surprised at the good result so far as non-recurrence is concerned. I think that, in sarcomatous conditions operated upon early, we should always expect good results. Rarely, in a case operated upon this early, do we look for dissemination of extravasation of the tumor cells out into the tissues. Sarcomatous growths differ from others in having a strong intercellular stroma that fixes the cells, one to another, whereas tumors of epithelial origin have no intercellular substance other than that which holds them together by agglutination; they are very destructive to cells with which they come in contact, and the cells which have degenerated get out of the way, so to speak, and the growth is disseminated out into the tissues especially in the direction of least resistance. The dissemination is early and rapid, very frequently traveling far and wide from the original location of the epithelial growth. Therefore, we do not expect good results from the removal of epithelial tumors, because we do not know widely they have become disseminated into the surrounding tissues. On the other hand, in sarcomata, this intercellular stroma holds the cells together, and rarely do we have any dissemination of the growth. This stroma, binding the cells one to another, is so strong that the tumor grows as a mass, and instead of dissemination we have a dissecting of the anatomical plane. In other words, a sarcoma begins as an encapsulated tumor, and only disseminates when the cells, by retrogression, growing so rapidly as to outgrow the intercellular stroma, are not so closely held together. Then we have dissemination, but, as a rule, sarcomata do not disseminate back into the structures; they grow away from them, in the direction of least resistance.

REPORT OF CASES.

By C. T. WOLFE, Louisville.

CASE I.—BILATERAL ABDUCTOR PARALYSIS.

James K., colored, age 49. Referred to me by Dr. Ray about 5 weeks ago with the following symptoms and history: That for several weeks previous to his coming he had some dyspnea which was aggravated by the least exertion. This was accompanied by a marked stridor during sleep. His voice was husky and an examination of his larynx gave the characteristic picture. The cords having assumed a fixed position in the median line with but slight opening between them during inspiration. There was no evidence of an acute inflammation. The epiglottis and mucous membrane was normal and the vocal cords white.

His urine was acid in reaction, clear, specific gravity 1022, no sugar or albumen.

Heart and lungs showed nothing abnormal.

He is a waiter by occupation and a moderate drinker. Gives a definite history of syphilis. Family history is negative.

The act of abduction is performed by the posterior crico-arytenoid muscles and in the majority of all cases lesions affecting these muscles are central in origin and arise from changes which are brought about by syphilis, bulbar paralysis and tubes dorsalis. However, instances are on record and one cited me by Dr. Ray in which bilateral involvement of the recurrent laryngeal nerves may be caused by pressure from goitre, aneurism, cancer of esophagus, etc. This man is improving markedly under mixed treatment.

CASE II.—HYSTERICAL APHONIA.

Mrs. K., white, age 40. Came to clinic February 9, 1912, with complete aphonia, having lost her voice suddenly. Three months previous to that date she was affected suddenly in a similar manner, but in that instance her voice returned in three days. The laryngoscopic examination showed that the cords approximated well in the anterior three-fourths of the glottis with the posterior portion remaining open leaving a triangular opening between the cords in that location which pointed to an involvement of the arytenoid muscles. The cords are white and movable with the exception of the incomplete adduction just referred to.

Both personal and family history are negative, except that she displays a very nervous temperament which may be due to the fact that she is nearing the menopause.

In this case we can eliminate a central and peripheral lesion from the fact that if we were dealing with a true laryngeal paralysis instead of an hysterical one, which is not a true paralysis, we would have an affection of the abductor muscles while in this instance we are dealing with an adductor affection.

I might add that since this case was a rather confusing one a careful physical examination of chest was made through the kindness of Dr. Wm. Jenkins, and the necessary steps taken to make the differential diagnosis by exclusion.

DISCUSSION.

J. M. Ray: With reference to the point brought out by Dr. Hall, I saw the demonstration by Dr. White, to which he referred. However, several years ago I read a paper before this society in which I reported a number of these cases. I happened to have on hand at one time, three cases of one-sided complete recurrent laryngeal paralysis, and in those cases I observed that when the head was turned very far to the paralyzed side, the patient could talk, but could not when the head was turned to the opposite

side. I made this observation and published it in connection with the report mentioned. Turning the head to the paralyzed side brings about practically the same condition as pressure upon that side.

The case of the colored man presented by Dr. Wolfe is a very interesting one. This man came to my office about seven years ago. Dr. Lederman saw him and made diagnosis of bilateral abductor paralysis. He obtained a specific history and put the man on iodid of potash. He went away and no more was seen of him until he came back about a month ago with that peculiar crowing sound. I looked into his larynx, saw the condition present, and asked Dr. Wolfe if he would not take charge of the case, which he did.

I think the chances are that this is not a complete paralysis. If it was, he would not be able to breathe as well as he does.

Lemon says that the abductor fibres are the ones that are most easily and frequently affected; they are the first to become paralyzed from pressure and the last to disappear when the patient gets well. This man has improved under iodid of potash.

I recall a case that I saw at the City Hospital, in a man who had a large aneurism of the aorta. He had bilateral abductor paralysis with stenosis. Dr. Rodman, who lived here at that time, was on duty at the City Hospital, and he did a tracheotomy. However, the patient was not relieved, and died in two or three days from rupture of the aneurism.

Gaylord C. Hall: I have had the pleasure of looking at these cases. The first case is particularly interesting. This man unquestionably has abductor paralysis, and I think Dr. Wolfe is to be congratulated in that he did not have to do a tracheotomy. Tubes is the most common cause of this condition.

The second case I did not have an opportunity to examine, because the patient closed the upper part of the pharynx, occluding the larynx.

There is one thing I want to call attention to, because it is not published in the text-books and I never heard of it until I saw it demonstrated by Dr. John C. White, of Richmond, at the meeting of the A. M. A. The point is this: In cases where we have an abductor paralysis, that is, where inspiration fails to draw the cords up, gentle and firm pressure backwards, over the cricoid cartilage, will relax those muscles, improve the voice, and enable the patient to breathe much better and easier than otherwise. Suppose, for instance, that we are dealing with a recurrent laryngeal nerve paralysis of, say, the left vocal cord. That cord occupies a position midway between abduction and adduction. The patient is hoarse because he cannot get true approximation of the vocal cord in the median line. Therefore, pressure on that side of the larynx will bring the cord into a parallel line and will result in immediate improvement in the voice, relieve

the dyspnea and enable the patient to respire much more freely.

To sum up, pressure upon the same side as the paralyzed cord, in paralysis of one recurrent laryngeal nerve, will produce immediate improvement in the voice. Therefore, if pressure on the left side produces such improvement, we know that the paralysis is on that side. If, on the contrary, pressure on the right side produces improvement in the voice, we can conclude that the right cord is involved.

Curran Pope: Speaking to the case of hysterical aphonia, it may not be uninteresting to ask ourselves the question: Why should this patient select a symptom such as aphonia as a manifestation of hysteria?

The question as to the selection of hysterical symptoms is entirely a psychic one, and oftentimes upon investigation of the hidden recesses of the individual's mind, we find that aphonia is really based upon the idea that it is not advisable for the patient to speak for fear of divulging some secret, or uttering some thought that may not be consistent with the ordinary ethics of society. That is often the psychic mechanism that brings about hysterical aphonia, though frequently it is accidental as many of them are. The idea comes to the patient something like this: "If I should speak thus-and-so, it will bring about trouble. Therefore, I should not speak it, and in order to be sure of not speaking it, I will lose my voice." Consequently the patient suffers from hysterical aphonia. Some may question this upon the ground that some powerful stimulus will often restore the voice, but when this occurs it simply means that something of a powerful nature has overcome the inhibition that the patient has exercised upon the vocal apparatus. It relieves the aphonia but it does not cure it. It simply drives the inhibition exercised by the patient out of the field and restores the activity of the voice for the time being, but that inhibition will come back, possibly in some other way. However, a powerful stimulus will often relieve the actual condition of aphonia.

C. T. Wolfe, (Closing): I do not know of anything to be added to the discussion. I have tried everything I know of to get this woman to talk, but so far my efforts have not been successful.

So far as the first case is concerned, I am ready at all times to do a tracheotomy, but the improvement under specific treatment has been so marked that I do not think it will be necessary.

Acute Mastitis.—Eicher states that at Basel the woman's breasts after the birth of a child are kept constantly covered day and night with a little pad of gauze moistened with a 4 per cent. boric acid solution. A piece of rubber tissue overlaps the pad and sticks to the skin, and a towel is then laid over both breasts. The pads are renewed each time after the infant nurses.

SOME ABNORMAL OBSTETRICAL CASES.

By THOS. K. VANZANDT, Louisville.

CASE I.

Mrs. T., age 35, multipara, third pregnancy.

DIAGNOSIS.

Twins, at full term. First stage of labor about 6 hours. First child, spontaneous delivery. About three hours later, because of almost continuous pains and inability to deliver second child, I was called in the case.

EXAMINATION.

Os completely dilated, membranes ruptured, liquor amnii all drained away with uterus contracted down tight about fetus.

POSITION.

Right scapula anterior with prolapse of arm and funis. Fetus dead, no pulsation in cord. Spontaneous version or spontaneous evolution out of the question.

Prognosis grave for mother if delivery was delayed. Hemorrhage, rupture of uterus and infection important considerations. External combined, or internal version impossible because of absence of liquor amnii and firm contraction of uterus.

Decapitation seemed to be in order. Before attempting this the following manipulation was tried with success. Tape tied to prolapsed arm. Hand full of sterile vaseline carried into uterus and fetus thoroughly anointed. Version followed by delivery was finally accomplished. Mother made uneventful recovery.

CASE II.

Mrs. W., age 20, primipara

DIAGNOSIS.

L. O. A. at full term. Pelvic diameters normal

Everything seemed favorable for timely expulsion of child but labor did not advance properly. Recession of head between pains and distress at placental site pointed to the possibility of a short cord. Version being contraindicated, membranes were ruptured, manual expression begun and the forceps applied.

Fetus still born, unable to resuscitate. Cord measured 11 inches. The position of cord in relation to fetus was of interest. Cord extended from umbilicus under right arm, over right shoulder, around anterior surface of neck and down back. Observation made at time of expulsion of shoulders. Necessary to cut cord in order to complete delivery of trunk.

CASE III.

Mrs. S., age 25. Primipara.

DIAGNOSIS.

R. O. A., at seven months gestation.

Seen first at 3 p. m., on Saturday. Complained of considerable pain in back and lower abdomen, headache, nausea and anorexia. Was very nervous. Both legs very edematous and abdomen unusually large. Cervix slightly dilated.

Sunday at 10 a. m. was called hurriedly "She's got hysterics."

Typical eclamptic convulsion at 11 a. m. Ordered to hospital at once. While preparing her for delivery, she had another convulsion.

Urinalysis: specific gravity 1010, albumin abundant. Pulse 150, pressure 170. Examination revealed the fact that the internal os had disappeared and the external os was dilatable. Accouchment force was therefore promptly done and delivery accomplished with forceps. Mother recovered without having another eclamptic seizure.

Living child, weight seven pounds. Child was edematous all over, pitting on pressure wherever touched. Urine loaded with albumin. Child died on the sixth day. Post-mortem by Dr. Boldrick.

Of chief interest were hemorrhagic spots in liver and marked degenerative changes in kidneys.

DISCUSSION.

Edward Speidel: I will discuss only the first and third cases. I do not see the object of the introduction of vaseline in the first case. I have had cases quite frequently in which the waters had completely drained away—in fact, I recall a case that I reported to this society, with an occipito-posterior presentation, in which the waters had drained away and the head was down on the perineum, and in spite of that I was able to return the head into the uterus and perform version without rupture. If you know your anatomy and have the patient completely anesthetized, with the labor pains practically in abeyance there is very little danger of rupture of the uterus if we proceed slowly. In a case of twin pregnancy, it would stand to reason that the fetus is small, and with a transverse presentation and the cervix fully dilated, I think it would be comparatively easy to grasp the foot and bring it down, and perform version. The danger of introducing vaseline in these cases is the danger of infection, which is one that is well recognized. Under those circumstances, I would put the patient in the Trendelenburg position, allow half a gallon of normal saline solution to flow slowly into the vagina and uterus, and with the distention that occurs the child can be easily turned. I have never resorted to that, however, because I have been able to do version in these cases without any danger to the mother in the manner just indicated.

I am not an advocate of **accouchement force** in eclampsia. My treatment is venesection, and according to recent literature, this is becoming more and more popular. Especially if we have the patient in a hospital, we can at once make preparations for the withdrawal of at least a pint of blood from one arm, at the same time introducing a pint of normal saline solution into the other arm. As a general thing, after this procedure, we have the convulsions under control. As a rule, we find that under the influence of the eclamptic condition the cervix is either dilated or dilatable. Therefore, if I find that the patient's condition demands it, I resort to manual dilatation and version—all under surgical anesthesia.

I do not believe in the application of forceps at the superior strait in cases of this kind, because version is so easy, and can be accomplished so much more readily and with a greater degree of safety to the mother.

Of course, these are all disputed points, but I believe that a perusal of the world's recent literature will show that in the majority of clinics—in Berlin, Vienna, St. Petersburg, etc.—venesection is being largely employed in these cases. By removing a certain amount of blood from the patient you remove just that much poison. One point that has been impressed upon me is that we should do some definite surgical work in these complicated cases, instead of so much haphazard medical work, as we have done heretofore.

H. A. Davidson: The doctor is to be congratulated upon the outcome of the first case. I believe, with Dr. Speidel, that version could have been done in this case, because of the fact that the patient had a large uterus and, it being a twin pregnancy, the child was small. I recall a case of this kind that I saw in the city hospital. This woman had been in labor for forty hours before she was brought to the hospital, and it was necessary to do decapitation and evisceration.

As to the suggestion made by Dr. Speidel, in regard to introducing artificial amniotic fluid into the uterus, I would not want to try it. While normal salt solution is sterile, of course, still in passing through the vagina it would undoubtedly carry some germs up into the uterus, with its blood vessels open, ready to absorb them and cause septicaemia. Therefore, I do not think it would be advisable to carry out this procedure.

In the case of short cord, which the doctor reported, of course, there was nothing he could do under the circumstances. There was no doubt that pressure upon the fetal vessels had shut off the circulation.

I have never perspired so much in my life as in the case I mentioned in the beginning of this discussion. This woman was brought to the City Hospital one hot night in mid-summer. After I had decapitated the child and delivered the body, the worst part of it was to get the head. That was a time when we did not have the necessary

instruments for decapitation at the City Hospital, and I worked the best part of the night on that woman. She had been in labor forty hours, with a mid-wife working with her, and she was infected. She eventually died of septic infection. It was one of the hardest jobs I have ever tried to get the head after the body had been delivered.

J. Garland Sherrill: I do not know why it is that doctors who take an interest in obstetrics do not discuss these cases. My experience in former years in obstetrical work led me to the conclusion that perforation of the skull, decapitation and evisceration were operations that should be thrown out of the text-books and should never be employed. In the case of Dr. Davidson mentioned, I do not believe he would do the same thing at the present time. I did one craniotomy to deliver a woman in a case where the child was known to be dead, and I have never tried any surgical procedure that was quite as difficult. After the head was crushed it was very difficult to get the pieces out without damage to the mother. It was a very difficult operation and, I believe, more dangerous to the mother than a Cesarean section would have been. I now believe that, in cases where delivery is so difficult as to necessitate such procedure, it is better to do a Cesarean section, even though the child be dead.

H. A. Davidson: What would you do in a case where the woman had been in labor for forty hours and was infected?

J. Garland Sherrill: I believe I would do a Cesarean section there, control the infection and do an hysterectomy, because we never know how severe the infection is going to be. It is much better, of course, to do these operations before infection takes place, and give the patient her choice between Cesarean section and a very difficult delivery. I believe the former is safer for both the mother and the child.

I have always been interested in the subject of eclampsia, because one of the first cases I saw in private practice after leaving school was the wife of a physician with eclampsia. We were not able to do anything for her and the case made a strong impression upon me. I think Dr. Speidel's statement that venesection is strongly indicated in these cases is correct. We do not know the actual nature of the poison that causes all this trouble, but we do know that some of these patients who die of eclampsia do not show any marked evidence of kidney damage; in other words, while some of them are undoubtedly due to acute Bright's disease, the local symptoms are evidently caused by the intense toxemia. The poison is produced in the body, carried into the blood and there acts upon the nervous system, producing convulsions. Therefore, the convulsions are of toxic origin, and by removing a certain amount of blood we remove a proportionate amount of poison, which explains the benefit

these patients get from venesection. It may be that the prompt relief which we have for many years attributed to emptying the uterus was really due to the loss of blood. Not altogether, of course, because the removal of the foetus takes away a large amount of the toxic material that is being produced, thus not only removing some of the poison by bleeding, but also removing the cause of the toxemia.

Dr. Zinke, of Cincinnati, recently published a paper on this subject, showing a very low rate of mortality in these cases, and he depends almost entirely upon the administration of veratrum viride in very large and persistent doses. It is a remedy that is certainly worthy of consideration. Dr. Zinke is a surgeon and gynecologist, as well as an obstetrician, and he naturally leans to the surgical aspect of any question. He was one of the first to propose Cesarean section in a central implantation in placenta previa, and while he has to a certain extent abandoned the position he took upon that point, his views still do not coincide with those of the gentlemen who are now proposing Cesarean section in eclampsia, but rather holds to the use of veratrum viride in large doses. Possibly a combination of these two forms of treatment—venesection and veratrum viride, would give the best results.

Wm. Sanders: I was especially interested in the last case reported by the doctor. About a week ago I saw a very similar case, with recovery of both mother and child, and both are doing well so far. This was a woman weighing about ninety pounds and it was her fourth delivery. There was no oedema in either mother or child. I delivered her a few hours after I first saw her, at which time she was in an unconscious condition. There was considerable hemorrhage and her condition improved after delivery. I employed veratrum viride in 10 grain doses and brought her pulse down in a few hours. I gave her this dose every hour for two days and then decreased it to five drops. I delivered her at eleven o'clock and by four o'clock in the afternoon she had regained consciousness. She had two convulsions before delivery and two afterwards. I had a hard time resuscitating the baby. She was in the ninth month of her pregnancy.

W. C. Dugan: I am surprised that Dr. Van Zandt would even consider decapitation in the case he mentioned. If I understood him correctly, he said that this was a living child, and I do not believe we should ever take the life of a child in this day of progress. Old Dr. Meigs once did a craniotomy on his coachman's child, and when the child was delivered it cried. This made a great impression upon him and he told the class that he would never do another craniotomy. Cesarean section is so safe that, unless there is impaction that cannot be overcome it should always be done in these cases.

In regard to eclampsia, I have seen two cases in my time. One was in the daughter of a physi-

cian, who called another doctor and myself to see her after she had been delivered. She was having a convulsion when we arrived. I advised the use of opium, taking the position that there are three indications for the use of opium; first, it lessens the strength of the patient; second, it is one of the best of diuretics, and third, it creates free diaphoresis. These three indications were met in this case. The woman was put on opium and the respiration kept down to about ten per minute. She had excreted practically no urine for twenty-four hours. I remained there during the day and by evening she had passed quite a quantity of urine, and by the next morning she was passing plenty, and had no further trouble.

Of course, one case does not amount to anything, but I was so impressed with this one that, if I had a case in one near and dear to me, while I might employ other agents, I think I would use opium in some form.

T. K. Van Zandt, (Closing): I do not agree with some of the things that have been said. Of course, I agree with Dr. Dugan that decapitation of a living child is simply out of the question. In the case I referred to the child was dead.

In regard to the first case reported, these various surgical procedures are all right where you have the patient in a hospital, but under the circumstances it was impossible for me to do other than I did. I had worked with this woman, trying to do a simple version, for more than three hours, and I thought I knew how to do a version. I tried in every way possible, under deep anesthesia, but the head was wedged into a lateral implanted placenta. I could not get the arm up all the way; I would get it up part of the way and then it would come down again. A version I grant you, is easy where you have liquor amni present, or where the uterus will relax, which it would not in this case. Therefore, I was up against it and had to do something.

In regard to the last case, I tried Zinke's method, venesection with elimination, giving chloroform to control the convulsions, and then morphin. I also gave veratrum viride every hour or two. I remember one case in which I used veratrum viride in 15 drop doses; gave enema, did venesection and drew off a quart of blood, and did everything possible except to empty the uterus, and in spite of all this the woman died. We found the ureters very widely dilated after death.

One feature of interest in the case reported to-night was the fact that the child was oedematous all over.

MALIGNANT TUMOR IN ABDOMEN OF A CHILD.

By P. F. BARBOUR, Louisville.

(REPORT OF CASE.)

I wish to report a case which presented some diagnostic difficulties which were cleared up only by an exploratory operation.

February 3rd I was called to see R. L., age 4, suffering from severe pain at the umbilicus, on examination enlarged veins were very prominent over the abdomen, showing an obstruction to the return circulation of the blood, these had been noticed for two weeks. The liver was greatly and uniformly enlarged; it was not tender upon pressure; there were no enlarged nodules and the edges seemed normal. The spleen was slightly enlarged, abdomen was rather tense, heart and lungs normal, the appetite fair, bowels regular, sleep good, the urine strong in odor, but otherwise not abnormal.

It was thought that there was a mild grade of congestion of the liver causing its enlargement and pressing to a certain extent on the portal circulation and the inferior cava. He was given calomel followed by small doses of bichloride of mercury, to be continued for its effect upon the liver. Two days later the conditions were about the same, excepting that the pain was intermittent and very severe at times, the abdomen was quite distended and tympanitic, tongue clean. A prescription for carminatives with magnesia was ordered p. r. n., two days later the abdominal pain was better, and tympany and tenderness less marked, veins not so decided, pain was felt in the flexure of the right groin. A prescription was given combined sal soda, a small amount of paregoric and magnesia.

Ten days from the beginning of the trouble he was no better, the liver very large and bowels not acting freely. High colonic injections of oil were used, which brought away large hard masses; these were continued every day. February the 18th liver was very much enlarged, ascites had developed and the legs were swollen, the left somewhat more than the right. Urine free from albumen, traces of bile coloring matter.

A consultation was held with a surgeon to discuss an exploratory operation, the question to be decided was the relation between the very large liver, with absence of jaundice and the swollen legs. It was thought that the liver itself was pressing upon the inferior vena cava or that there was a tumor in the epigastric region, which could not be palpated.

Three weeks from the beginning of the illness a consultation was held with an internist, because the liver was apparently larger, limbs more swollen, abdomen much distend-

ed, respiration bad, apparently no ascites, some rigidity in the abdominal wall. Tentative diagnosis of tuberculous peritonitis and unguentum, hydrargyria was ordered.

One week later bowels acting freely, tumor mass becoming more elevated in the median line and pointing towards the navel, the liver is growing smaller, shape of the swelling changing. One week later plural effusion in the right side, child gradually weakening and emaciated. Examination of the blood was made to determine if the tumor could be a hydatid or an abscess. The report showed neither leucocystosis nor eosinophilia, thus excluding both of these conditions. Exploratory operation was suggested and was done on March 13th, 40 days from the beginning of the illness. The pleural effusion was drawn off and found to be bloody. Diagnosis, malignant tumor, was then confirmed by finding a large mass in the median line underneath the liver and pressing the liver forward so that the mass could not be distinguished from the liver by palpation. It was diagnosed a hyper-nephroma, but the condition of the child was so serious that extensive examination was not possible. The child gradually sank and died three weeks subsequently.

Of interest in the case is the history of malignant tumor on both sides of the family, but not in the immediate family.

DISCUSSION.

Wm. H. Wathen: This operation has shown such indefinite living pathology that from this alone it is impossible to say positively what the trouble was, but I do not think the history of the case, as given by Dr. Barbour, at all bears out the diagnosis of hypernephroma. In the first place, hypernephroma is of much longer duration than was indicated in this case, and the symptoms are entirely different. Before the tumor is apparent there is often blood in the urine, and this is markedly true as soon as the pelvis of the kidney is involved by the growth.

Hematuria may not appear for one or more years after the onset of hypernephroma, may then be only slight, and sometimes repeated at long intervals, the intervals finally becoming shorter and the hemorrhage more profuse. When the calyces and the pelvis becomes seriously involved by the tumor growth, the bleeding may be profuse and even continuous, the patient now loses flesh and a general decline in health begins. The disease may continue from two to five years after the first symptoms. Hypernephroma never occurs in infancy or early childhood and the cases reported at this age are clinical and pathologic errors. The disease seldom if ever begins before the age of 20 years, and is as carcinoma and sarcoma, more frequent after the age of 30. The case reported by Dr. Barbour is an embryonic mixed tumor of the kidney which had its

origin in embryonic islets or rests. Fifty per cent. of these tumors are found in children under three years of age and but few cases are reported after the age of ten. They are intensely malignant, of rapid growth and the patient seldom lives one year after the diagnosis of kidney trouble. They cause no hemorrhage because the growth does not invade the pelvis as in hypernephroma, the growth being nearly entirely evertive. These tumors become so soon attached to all adjacent structures that they are inoperable unless treated in the early stage. I have recently operated on a case of embryonic mixed tumor of the kidney, and also on a patient for a large hypernephroma which had existed for more than five years.

J. Garland Sherrill: Although the gentlemen present at this operation should be the best judges of the origin of the tumor, and also the character of the growth, I must confess that a tumor in the median line, growing slowly and pushing the liver structure forward, is more likely to be a sarcoma of the retroperitoneal glands than to have its origin in the kidney or the suprarenal tissue. It is true that tumors springing from the right kidney are sometimes pushed forward, but as a rule they appear more in the flank than in the median line. Furthermore, in examining a patient with a tumor of the kidney, we are likely to find that the tumor can be pushed back into the line from which it springs.

It is not unusual to see very large kidney tumors in infants, which are sometimes sarcomata and sometimes hypernephromata. Sarcomata grow more rapidly than hypernephromata. I recall a case in the care of the late Dr. George W. Griffith, in which a child had an enormous tumor, extending from the left kidney to far beyond the median line. The child died as a result of the growth. The late Dr. Cartledge also reported a case of this kind.

Hypernephromata are tumors that are not very well understood, and while it is true that hematuria is a very early symptom, as a rule, yet in many cases the tumor exists for some time before haematuria manifests itself. Persistent haematuria in a child should always lead us to suspect such a tumor, as they are by no means rare in children.

I do not think the gentlemen should be criticised too strongly for not having made an accurate diagnosis after opening the abdomen because, as Dr. Barbour has said, the patient was in *extremis*, and after ascertaining that the tumor was malignant, the only thing to do to save the patient was to close the abdomen as quickly as possible.

W. C. Dugan: I do not think this was a tumor of the kidney at all. I have never seen a tumor of the kidney press upon the portal vein to such an extent as indicated by Dr. Barbour. The fact that the tumor grew upwards into the chest, it

seems to me, practically excludes tumor of the kidney. Tumors of the kidney invariably grow in the line of least resistance, and the pressure upon the portal circulation in this case indicates, to my mind, the post-peritoneal origin of the tumor.

It is very difficult to say positively just what the nature of the growth was. I think it was a sarcoma, but I cannot say just what structures were involved.

P. F. Barbour, (Closing): The point of greatest interest to me in this case was the elimination of various conditions in arriving at a diagnosis. The operator gave it as his opinion, at the time of operation, that it was an hypernephroma. After recognizing the condition, he closed the abdomen as quickly as possible, which was necessary in order to save the child's life. I was not enough of a surgeon to be able to make the diagnosis myself.

REPORT OF CASE FOR DIAGNOSIS.

By W. C. DUGAN, Louisville.

The condition you see in the patient presented to-night began in January last. At first she had a small blister on the heel, and this ulceration, which is just over the internal malleolus, developed some time later. When she first came under observation it was about one-third of its present size, and the skin for two inches around was distended with pus. This has all disappeared, but she now has a condition that will not heal. The fluid which you see is not pus; it has been examined microscopically and contains no pus cells. I do not know what it is, and I do not know to what the condition is due. Practically every form of treatment recommended for such conditions has been tried, but it will not heal.

DISCUSSION.

M. L. Ravitch: This case of Dr. Dugan's is a very remarkable one. It is neither a tubercular nor a specific ulcer. It is a case of sporotrichosis. It is a very rare disease and only a few cases were reported in Europe and in this country. Animals suffer from it. It resembles glanders. A few cases were reported by Dr. Hyde of Chicago. This is a typical case with its granulating floor, discharging characteristic sero-pus. From stained smears you may get pus cells with accidental staphylococci but not organisms of any kind. Blood cultures carefully made will reveal the sporotrix of Schenkii. Carettment or brewers' yeast are the rational remedies. X-ray may be tried.

W. Edgar Fallis: The bacterium in this secretion is the most peculiar I have ever seen. It is a diplococcus, and the gross appearance of the culture is exactly similar to that of the staphylococcus albus. The secretion contains no pus cells; I was unable to find one pus cell in eight or ten

slides made from this material. This bacterium will not grow on blood serum; it will grow only on nutrient agar. It will not grow on litmus lactose. It is a diplococcus that looks exactly like the gonococcus; without a differential stain they could not be told apart. We made about six attempts to grow this bacterium and succeeded in only one instance.

I believe the Wasserman reaction would throw some light on this case; at least, it would do no harm to try it.

W. C. Dugan, (Closing): This condition is absolutely painless. When she first came under my observation, it was a large, angry-looking sore, but it was not tender in the least. I thought it would disappear in a short time, but instead of improving it gradually grew worse, in spite of every form of treatment that I could think of.

VACCINE TREATMENT IN FIVE CASES OF PYOSALPINX.

By H. J. FARBACH, Louisville.

CASE I.

Miss E. B., age 22, mistress. One abortion two years ago followed by curettage. No subsequent menstrual disturbance or irregularity. Contracted gonorrhea two months ago. Careless treatment, pain and bearing down feeling for a week. Twenty-four hours ago was taken with severe pain in left ovarian region. Pain intense, radiating down the thigh and up into breast, lower abdomen and left side rigid and very tender. Attempt at bimanual examination caused so much pain it had to be abandoned. Temperature 102.5, pulse 130. Anti-gonococci serum and stock gonococci vaccine given and culture made from discharge. Culture showed gonococci and colon bacilli. Anti-gonococci serum in four c.c. doses repeated every four hours until sixteen c.c. were given. Pain relieved but pulse and temperature remain high. Autogenous vaccine given on the third day was followed by complete relief of symptoms except discharge and tenderness on the left side on bi-manual palpation. Patient left bed thirty-six hours after third injection. Discharge and all symptoms disappeared after the fifth injection.

CASE II.

Mrs. W., age 30, married; healthy child four years old. Numerous miscarriages since birth of living child. Last one seven weeks ago. Present condition began ten days after miscarriage. Temperature 104, pulse 130. Pronounced septic sweat necessitating change of clothing and bed linen every hour. Profuse vaginal discharge, sanguineous and foul. Lower abdomen rigid and tender, cervix large and soft, uterus large and fixed. Culture showed streptococci, staphylococci and colon

bacilli. Condition so serious I did not feel justified in waiting for preparation of autogenous vaccine. Gave injection of stock vaccine known as Van Cott. Fifteen hours later temperature 101, pulse 108. Sweat greatly diminished. Second injection the fifth day. Twelve hours afterward temperature 100, pulse 90. No sweat. Vaginal discharge still profuse but not so foul. No pain, rigidity less. Expressed a desire for food. Following third injection temperature dropped to 99, pulse 80. Discharge ceased. Rigidity entirely gone, very slight tenderness on pressure, uterus and tubes still large but soft and fairly movable. Between fourth and fifth injection patient had a normal menses. Examination after the fifth injection showed uterus still large but freely movable; tubes but slightly enlarged and not painful; very little discharge from cervix. Patient left city at this time feeling perfectly well, having gained twenty pounds in four weeks. Advised at least three more injections. Report from patient three months later states in best of health and menses regular and normal. The stock vaccine was used throughout in this case.

CASE III.

Mrs. L., widow, age 28. Two healthy children, five and six years old. Double salpingo-oophorectomy two years ago. Still suffers severely from menopause syndrome. Profuse uterine discharge. Culture shows gonococci and staphylococci. Autogenous vaccine made. Patient discharged after fifth injection. No return of trouble in three months.

CASE IV.

Miss E., prostitute, age 23. History of attacks of pelvic trouble for three years. Last severe attack two months ago. Confined to bed for two weeks. Present symptoms backache, occipital discharge, loss of strength and weight, occasional sweat. Bi-manual examination shows large tender tube on right side, uterus large and partially fixed, thick,ropy, yellow discharge in cervix. Autogenous vaccine made. After sixth injection there were no symptoms except a thin clear discharge from cervix occasionally.

CASE V.

H. D., single, age 23, living at home. No symptoms except vaginal discharge and vague pain below Poupart's ligament on left side. Gave no history of an acute attack at any time. History as to length of time present symptoms had been present indefinite. Being a gonococci carrier was proven beyond a doubt. Examination of cervical discharge showed colon bacilli, gonococci and staphylococci. All symptoms disappeared after

third injection of autogenous vaccine. Six injections were given in all.

This is not a report of the vaccine treatment of pus conditions in the female generative tract but of the use of vaccines in the treatment of this condition. Candidly, I do not believe that vaccines by themselves would have accomplished the results, neither do I believe that other measures without the vaccines would have resulted the same. Such measures as drainage, position, local applications, douches, opium medication and uterine are indispensable. And as much depends on their proper application as on the vaccine.

The indiscriminate destruction of the female generative tract followed as it invariably is by a series of symptoms, often more severe and distressing than those present before the operation, is the principal reason for the suggestion of this line of treatment. In another report I have taken up in detail different phases of the procedure that I can not take up here, but I wish to emphasize these few points.

1. That evidence of pus in the tube, uterus or ovary is not an imperative indication for the removal of these structures any more than it is for the removal of the analogous pathology in the male.

2. That often the symptoms produced by the precipitated menopause are more distressing, and I might say more dangerous, than those of the pyosalpinx.

3. That I have seen cases illustrating every stage of these pathological conditions and due to all sorts of infectious agents and I have yet to see one that was not relieved, or, at least decidedly benefited, by this simple procedure.

4. That contrary to certain opinions it is not only a temporary partial relief, but in my experience the results have been permanent and the relief complete.

Autogenous vaccines, of course, promise more than stock vaccines, but in one of these cases a stock vaccine was used with equally good results.

The injection is subcutaneous, the dose depends on the resistance of the patient and the virulence of the offending organism. The repetition of the dose depends on clinical symptoms.

The complement fixation phenomena has made it possible to demonstrate that specific antibodies appear in the circulation within thirty-six hours after the injection of the vaccine and increase for several days. I have had evidence of their presence in the circulation six months after the last injection. One symptom of the so-called negative phase that follows the injection in these conditions is interesting and present in nearly all cases. It is the appearance of a bloody discharge

from the uterus, sometimes profuse. It was present in all five of these cases, even the one in which the tubes and ovaries had been removed two years before.

DISCUSSION.

Geo. H. Day: I do not think there is any class of cases in which the indications for vaccine treatment are more marked than in this class. I have seen two cases in which, in my opinion, the vaccine treatment was indicated. One of these was a woman who had been married for twenty years, and had been operated upon for the removal of the tube and ovary on one side. She was having a great deal of trouble but was very much opposed to having the other tube and ovary removed, and I decided to try vaccine treatment as a last resort. I can truthfully say that I never saw anything work as beautifully as a stock vaccine did in this case. That was three or four months ago and she has not had the slightest return of any of the symptoms. Previous to this treatment she had the most profuse leucorrhea I believe I ever saw, and her abdominal symptoms were very severe.

Another case was in a prostitute, who had undergone a series of operations, curettements, etc., but who would never consent to the removal of any of her abdominal organs. She has been getting an autogenous vaccine for fifteen days, and at the present time she is in pretty good shape.

I am convinced that, in this particular class of cases, we can expect a good deal more in the future than we have accomplished in the past, with the aid of vaccine treatment, and I think that in all such cases we should give the patient the benefit of the doubt and administer a proper vaccine.

J. Hunter Peak: I am always exceedingly interested in any report that Dr. Farbach makes, because I know he does good work and thoroughly studies his cases. However, in this class of cases, particularly gonorrheal pus tubes, I have very serious doubts whether a very badly diseased tube can ever be made useful so far as the function of child bearing is concerned. It is not always necessary to sacrifice the ovaries when the tubes are removed, unless the former organs are extensively involved, and inasmuch as an operation will positively relieve a salpingitis, I cannot understand why the patient should be exposed to the serious danger of infection other than the gonococcus, unless the vaccine treatment is to be given in conjunction with operative measures and drainage. We know that in gonorrheal salpingitis, the tubes very rarely rupture, as the appendix often does; they can stand a good deal more inflammation than the appendix; their location enables Nature to protect them by adhesions. Therefore, particularly in gonorrheal conditions of this kind, there is very little danger in waiting; in fact, I think it is sometimes best to delay operation for a while, and while

we are waiting for the condition to become what might be termed chronic, it may be a good idea to administer a vaccine. I am not one who would advocate the removal of any organ unnecessarily; each of the various organs is placed there for a physiological purpose and none of them should be removed that can be saved.

I wish to congratulate Dr. Farbach upon the apparent success which has attended his efforts in these cases, but I would certainly advise him to keep track of them, and see if the pathology has all disappeared. He may find later, in some of these cases, that the uterus is still fixed, and that there is still evidence of the existence of adhesions which may sooner or later cause the patient a good deal of trouble. If he does not, it will certainly be an encouragement to continue along this line of treatment. It would be interesting to hear a further report on these cases at some future time, as to the progress they have made.

Jno. B. Richardson, Jr.: I would like for Dr. Farbach to tell us, in closing, in what class of cases he would advise the use of vaccines? I have in mind a picture of a case of pus tubes, with Nature making every effort to take care of the condition, but where a little nudue exercise on the part of the patient may cause rupture of the tube, followed by general peritonitis and possibly death. Would he employ vaccine in a case of that kind? Or would he give the patient the benefit of the doubt and advise operation?

I do not wish to be misunderstood as deerying the use of vaccines in these cases, but it appears to me that it would be a little difficult to decide in what class of cases they should be employed.

Chas. W. Hibbitt: I am very glad to have heard the report made by Dr. Farbach. I believe that the use of vaccines will prove to be a great aid to the gynecologist in eradicating the gonococic infection especially, from the uterus and cervix, but I question whether we can entirely exclude surgical procedures and get any very pronounced results.

One case he reported struck me as being a very remarkable one. If I understood him correctly, he said that the uterus was fixed as the result of an acute or chronic inflammation, probably pus-tubes with adhesions protecting the surrounding structures, and after the use of vaccine, at the next examination the uterus was movable and had decreased in size. I cannot see how the vaccine could have relieved the adhesions in the pelvis and allowed the uterus to become movable.

H. J. Farbach, (Closing): I do not think that any one present would advocate the removal of a testicle or an epididymus in the male for any but a tuberculous infection, or malignancy, and still, from an anatomical and physiological standpoint, the tube and female testicle if you will, while they have every advantage over the male organ in the way of drainage, are removed on the least provocation. The female tube is

straight while the male tube is somewhat tortuous.

In the first case in which I used this treatment, about five years ago, I did not think it was indicated but administered it as a last resort. This woman had been advised by two or three men to have an operation performed, and after my examination I advised the same thing, but she was the daughter of a prominent man and the sister of a physician, and an operation would have meant a confession of licentious tendencies which she did not want to confess. She said she would rather die than undergo such an operation. In that case the results were remarkable indeed.

In regard to Dr. Hibbitt's remarks, I will say that, where there are chronic adhesions fixing the uterus, no medication in the world will do any good, but where the adhesions are due to an acute inflammatory process and exudation, the administration of vaccine will relieve them.

The point I particularly wanted to bring out is this: The results are not due to the opsonic influence of the vaccine; it is the production of antibodies that does the work. In other words, from an opsonic standpoint, we are going squarely in the face of the advice given us by the originators of opsono-therapy. While in any acute condition, Nature is producing all the opsonins possible, she is not so active in the production of antibodies. The object of the vaccine administration is to increase the number of leucocytes, first the mononuclears and then the polynuclears. Then the antibodies are produced either from the leucocytes, the spleen or the lymphatics. The latter is probably the best explanation.

After the administration of the vaccine the patient must be kept quiet for 36 hours. In some of the first cases I treated, I kept the patients in bed for two weeks after they had no symptoms from their standpoint. They would come to the office for an injection and I would advise them to go home and go to bed for 36 hours. They would fail to do this and, consequently, would have seemingly an acute attack of the trouble—severe pain, a rise in temperature, and all the symptoms of an acute attack of salpingitis, whereas in those that had remained quiet this did not occur.

One of the most spectacular symptoms following the administration of vaccine is a bloody discharge. In most of these cases (25 out of 30), the patient has had a bloody discharge within the first twenty-four hours following the injection. In most cases this is not present after the second or third injection, but in some instances it continues.

I remember one case in particular where the vaccine did not seem to be doing any good, and I advised the patient to consult a surgeon, who emphatically said that her condition was too acute to allow her to go upon the operating table at that time, and to let him hear from her

later on. Three weeks later I sent this patient to his office and he called me up and said there were no indications for operation at that time.

RHEUMATISM PHYLACOGEN.

(CASE REPORT.)

By J. T. DUNN, Louisville.

The history of rheumatism phylacogen is not necessary in this paper. That Parke, Davis & Co., reports favorably upon the Shafer method of treating disease should be sufficient warrant for us to take notice. They report cures in 96 per cent of a test list of more than 100 cases. That alone would cause most rheumatic patients to welcome the new remedy.

That a proper diagnosis should be made goes without saying. We have been advised to use it in those cases where all forms of septic arthritis, especially gonorrheal in origin, have been ruled out.

There are two methods of administering rheumatism phylacogen, and, owing to the violent reaction which ensues when the intravenous method is resorted to, we are cautioned to use only the subcutaneous method; if, however, failure rewards our efforts, then resort to the intravenous route.

There are some advantages and disadvantages in both. Cases with heart lesions, or arteriosclerosis, or those far advanced and near the end of life, should not receive the intravenous treatment. There are no contraindications to the subcutaneous administration.

There are some objectionable features coupled with both methods of administration. For instance, considerable complaint is made of pain at the point of injection by the subcutaneous method, where there will be no pain or discomfort if given intravenously; and where a dose is administered daily as in this treatment, the patient becomes so sore and tender that it is difficult to continue the treatment. The indurations produced by the subcutaneous method have, in my experience, been persistent and painful. The intravenous administration, if the proper technique is used, is no more painful than the ordinary hypodermic injection, and the local reaction is nil.

Overdosage by the intravenous method is possible, and will be indicated by the very explosive effect which follows within a very few minutes after its administration; to-wit, violent, chattering chills, bigness of lips and fingers, and severe vomiting, followed in three or four hours by hyperpyrexia. The minimum dose should be given first, and gradually increased. The deposit of the selected dose within the vein must be very gradual, and at no time should more than one c.c. be given per minute, allowing ten c.c. to be administered

in ten minutes. This precaution will prevent the occurrence of many alarming symptoms.

Considerable skill is required in the introduction of the needle within the vein, which should be done by simple puncture and not by open incision, as was formerly advised.

The subcutaneous method is so simple that any one accustomed to hypodermic medication will have no hesitation in practicing this method of administering phylacogen. The intravenous method is a purely surgical procedure and should not be attempted by those not familiar with surgical technique. The introduction of a bubble of air, or a blood-clot, within the vein, would prove serious. Within ten seconds after the arm has been prepared with the customary cleansing solution, and the veins made to inflate by some constricting agent applied about the arm between the elbow and the shoulder, the injection should begin. A very sharp hypodermic needle, about 26 gauge, should be used, and it should be detached from the syringe until introduced within the vein. We are to know when the vein is entered by the passage of blood through the needle, which has been obliquely passed through the skin and into the proximal wall of the vein, taking care not to pass entirely through the distal wall of the vein and out into the underlying tissues. With a sharp needle, no difficulty is encountered if the veins are of any size. As the blood flows from the needle, the loaded syringe, previously prepared so that no air is present, is connected directly to the needle, and the slow administration begins. If you have entered the vein and have not withdrawn the needle in your efforts to connect the syringe, the fluid enters the vein direct and there will be no discomfort as its administration ensues; otherwise, it will be necessary to begin over again. Again, so much time may be consumed in making the connection between the syringe and the needle, that the blood will have clotted and blocked the needle, and a delay occasioned.

The reaction following the subcutaneous administration is very mild, and at the most consists of slight chill, and medium elevation of temperature, say about 103 degrees F., reaching its highest point within six or eight hours; whereas, the intravenous reaction occurs regularly within twenty minutes, beginning with a marked chill, soon followed by vomiting, and, within three or four hours, a temperature much higher than 103; in some instances 106 to 108. The chills and vomiting pass off within 30 to 40 minutes, perspiration becomes profuse and the patient is inclined to sleep, only to awaken free from pain. This freedom from pain frequently follows the administra-

tion of the first dose if given by the intravenous method.

REPORT OF CASE.

Mrs. V. G., age 27 years. Ill of rheumatism ten years, commencing in right knee, followed soon by the left. Were very much swollen, red and painful. One year ago both shoulders, elbows and wrists, with three fingers and thumb on left hand and thumb only on right hand became affected. The left wrist became so stiff that motion was almost entirely lost and the motion in all the other affected joints limited to about 50 per cent. than normal range.

The customary rheumatic treatment was resorted to, in addition to 5 weeks at Hot Springs, Ark., 3 months at Martinville in 1911, and another 3 months in 1912, and in the interval frequent trips were made to various parts of the country where hopes of relief would be obtained including Saratoga Springs, Mt. Clemens, Clark's Baths, Detroit, Mich., and French Lick, etc., etc., all to no avail. The progress of the disease was not checked, nor were the pains relieved. The only relief obtainable was by free use of aspirin and at the least calculation the patient has taken 6,500 grains of aspirin since last June (now 11 months) and by actual count has taken 6,000 grains in past eight months, or about 25 grains per day.

For one year she has been obliged to use a cane in walking and since the arms became involved one year ago has been helpless insofar as dressing, feeding herself, combing her hair, etc., as is impossible to get the hands to the head or mouth.

Admitted to hospital April 24, 1912, walking with difficulty by aid of cane, both knees firmly bandaged with flannel and very painful. The use of pillows under and between the knees were necessary. Patient unable to move herself the slightest, the service of a special nurse being needed to make all the necessary movements for the patient who declared that rheumatism was "a most difficult quest to entertain."

Charts showing the range of motion in both upper and lower limbs were made upon admission to which you are referred.

Temperature 98 2-5 degrees. Pulse 84. Respiration 20.

April 24th, 10:00 a. m., 5 c.c. rheumatism phylacogen was administered subcutaneously beneath the left scapula. The only reactionary symptoms were elevation of temperature and pulse which began in three hours and increased until temperature of 102 and pulse 112 were recorded in eight hours, when they fell gradually to normal. Patient complained of soreness at site of injection, but had a fairly good night.

April 25th, 8:45 a. m., 5 c.c., subcutaneously in right hypogastric region (the back being too sore to admit of further medication). The reaction reached its height within 11 hours, temperature being 101 3-5 and pulse 106. Had a good night's sleep but complained of pain at site of injection (no relief from pain).

April 26th, 9:45 a. m., 10 c.c. given in left hypogastric region and at 10:45 had cold clammy perspiration with chilly sensation, heat applied. The reaction reached its height in 9 hours, temperature being 104 1-5, pulse 120. Fairly good night, no relief from pain.

April 27th, 9:15 a. m., 10 c.c. given in right hypochondriac region and the reaction reached its height within 10 hours, temperature being 101 4-5, pulse 122, and had a fairly good night. No relief from pain. (Here decision to give intravenously).

April 28th, 9:15 a. m., 5 c.c. intravenously. Reaction began to show in 20 minutes by marked chill which was a severe clatter, not only causing the patient to tremble from head to foot, but the bed was thrown into a state of vibration such as we had never seen. The chill continued for 35 minutes and was accompanied by blueness of lips, ashy hue of face and frequent outbreaks of cries by patient of pains in the affected joints, interspersed with vomiting lasting 20 minutes and was projectile in character. Hot water bottles and additional covers were resorted to and as the chill passed off, hot lemonade administered, but promptly ejected because thirsty and uncomfortable. Patient lapsed into drowsy condition, but did not sleep. Reaction reached its height in 3 1-2 hours, temperature 106, pulse 136, respiration 39, and within 11 hours had dropped to temperature 101 4-5, pulse 126, respiration 30. Body profusely bathed in perspiration; slept fairly well and awakened free from pain. To our great surprise and delight, patient was able to change her position from side to side at will without the slightest pain and marked improvement in range of joint action was noted, there being about 25 per cent improvement. General condition much improved; patient now able to easily reach the mouth, hair and any portion of the body without pain, and as a demonstration kicked both feet at one time into the air making flexion and extension without pain, and has continued to improve from that day (April 29th) notwithstanding the continued rainy weather.

The day following the first intravenous injection none was given. Upon this day she was very comfortable and sat up in a chair two hours in the afternoon without pain or discomfort other than stiffness of joints.

April 30th, 9:00 a. m., 8 c.c. intravenously, followed in 20 minutes by the typical reaction

as before described, chill, vomiting, sweating, except not so severe, temperature reaching only 102, pulse 120; slept well.

May 1st, 8:45 a. m., 10 c.c. intravenously, followed in 20 minutes by typical reaction, temperature 102 3-5, pulse 114. Slept well and feeling better.

Attention is called to herpes upon right cheek, size of half dollar, and two points upon back low down, same size, attributed to phylacogen, and approaching menstrual period which appeared the following day. No phylacogen given during that period and zinc oxide ointment applied locally; herpes all disappeared when menstrual period was over. During this rest from treatment patient's appetite improved very much and spent most of her days in wheel chair and short walks about the hospital, supported by the nurse, going out in the yard when weather conditions were suitable, sleeping better and free from pain.

May 6th, 9:00 a. m., 8 c.c. intravenously, followed promptly with the regular type of reaction, temperature reaching only 103 4-5, pulse 130 within 3 hours and 45 minutes, and soon receded. Patient feeling better at 2 p. m., sitting up in bed at 6 p. m., enjoyed supper at 9 p. m., and up walking about the room and hall at 9:30 p. m., and retired at 11 p. m. Still complaining of soreness and presenting some discoloration over site of previous subcutaneous injections.

May 7th, 9:15 a. m., 10 c.c. intravenously, followed by typical reaction, temperature reaching its highest within 3 hours, being 103 2-5, pulse 124, patient up in chair at 3 p. m.

Dismissed from hospital May 8th.

May 9th, 9 a. m., 10 c.c. intravenously.

May 10th, 9 a. m., 10 c.c. intravenously.

Making a total of 9 packages of 10 c.c. each, covering a period of 17 days.

The patient is highly pleased over the outcome of the treatment and is now, even in this short time, able to sleep better, eat better, walk without pain and unaided, goes every place about the home, dresses herself, combs her hair, feeds herself, and all without the use of aspirin as she discontinued its administration May 8th, and has felt no inclination to resume its use; has discarded the flannel bandages and her faithful friend the cane has an honored place upon the hall tree.

It is useless to say that so far we are very much pleased with rheumatism phylacogen. It is certainly a boon to this painful class of sufferers and although the reaction from its intravenous administration is severe, it is to be preferred in suitable cases to the subcutaneous method. Note the difference in the physical condition in this case report where subcutaneous injections, even in 10 c.c. doses,

did not lessen the painful condition of joints, whereas the very first intravenous, consisting of only 5 c.c., gave immediate relief. It is true that intravenous medication is a surgical procedure and should be given only by physicians accustomed to surgical cleanliness and surgical technique. I believe it is perfectly safe in the hands of such men; others should use the subcutaneous method and give the treatment for a longer period and be satisfied with slower results.

DISCUSSION.

Edward B. Richey: I have been very much interested in this report. Perhaps some of the members present will remember a case that I reported to the society some time ago, in which I used the same treatment. I notice that there are many points of similarity between Dr. Dunn's case and my own; namely, the severity and long standing of the condition, and the various efforts made for its relief. However, there is considerable difference in the ages of the patients; the lady under my care was farther along in years than Dr. Dunn's patient.

I disagree with Dr. Dunn with respect to one or two points in connection with the administration of phylacogen. In other respects I agree with him entirely. The experience I have had warrants the statement that in every case of the kind that comes to me in the future, I will not hesitate to use the intravenous method. I believe it is an entire waste of time to use the subcutaneous method. It makes the patient miserable and uncomfortable and has a tendency to make them become dissatisfied with the treatment. The number of injections makes a multiplicity of sore places, and human nature rebels against getting the body into this condition. The fact that the intravenous injection gives practically no pain makes the patient welcome it as quite a boon after having experienced the subcutaneous injections for a while. However, I believe I prefer the method of leaving the needle attached to the syringe after introducing it into the vein. It seems to me that it is more convenient and there is less danger of the needle becoming clogged with blood before we are ready to introduce the fluid.

The way that I tell that I am in the vein is this: After introducing the needle, I withdraw the plunger of the syringe until blood appears in the anterior portion of it and then, by raising the plunger and allowing the air to pass into the upper portion, there is no danger of introducing air into the vein. After having been convinced that the needle is in the vein by drawing a portion of the blood, I introduce the phylacogen.

I have never had any trouble in getting the needle into the vein. I usually take about five minutes for an injection.

I notice that Dr. Dunn began with 5 c.c. as the first dose. I began with 2 c.c., because the

treatment was new to me and I did not know what the results would be. I had read that the reaction was very severe; consequently, I began with the smaller dose. After seeing that the reaction was not so severe, I felt justified in increasing the dosage gradually from m2 c.c. to 5 c.c., then to 7 1-2 and then to 10 c.c. After having tried three subcutaneous administrations, I began intravenous injections. The results in this case, which has been under my observation since the first of February, have been nothing short of marvelous to me as well as to the patient herself. She had been unable to move; an attendant had to lift her from her chair to bed. She weighed over two hundred pounds and had not been able to walk, or even to get out of bed, for a number of months. She had been suffering with the disease for twelve years, and had tried all sorts of treatment. After the first injection of phylacogen, the same results were evident that Dr. Dunn mentioned in his case. She could turn over in bed without assistance and without pain. This improvement continued and in ten days after she came to the city she was in condition to go back home. She could have walked on her crutches at that time, but I preferred to send her in a wheel-chair in order to avoid any accident. I saw her yesterday. She is delighted with her physical progress and thinks there is nothing like the treatment given her, although she says she cannot forget how severe the reaction was. She is walking everywhere with the assistance of her crutches, and she can walk a few steps without her crutches but prefers not to risk it, for fear that she might fall and break a limb. The very fact that this patient is free from pain, even if no other results had been obtained, is sufficient to justify the treatment.

Thos. K. VanZandt: I would like to ask Dr. Dunn if he would advise this treatment in the milder forms of rheumatism, or only in the more severe cases?

Bernard J. O'Connor: I have not had any experience with this agent, but it seems to me that it should be employed as a dernier resort rather than the first thing we think of in the treatment of rheumatism.

There are one or two questions I would like to ask. First, what is the reason for the use of a toxic agent (as this apparently is) in the treatment of rheumatism? Second, why should it be given daily instead of allowing several days to elapse between doses? Third, do the results of studies of the blood (if any have been made) tend to show any curative effect in the way of increased leucocytosis, an increase in the opsonins, or any increase in the defensive properties of the blood serum?

W. A. Bolling: I will reply to Dr. B. J. O'Connor's questions seriatim:

1st. Phylacogens are not toxins in the sense of toxins which are injected into animals for the production of antitoxins. Phylacogens are nei-

ther "bacterial vaccines" nor "sera" as these terms are usually understood. They are sterile aqueous solutions of metabolic substances generated by bacteria grown in artificial media, as the name phylacogen indicates, which is derived from two Greek words, a guard and to produce or "phylaxis producer."

2nd. The necessity of daily administration of phylacogen is to produce a permanent immunity or neutralization to prevent relapse, however there are certain indications such as great prostration and intense local and systemic reaction following the injection of a large dose of phylacogen, which would warrant a longer interval between doses 36 to 48 hours, however these conditions are unusual and it is not advisable to extend the interval of rest between doses longer than 48 hours.

3rd. The hematological studies demonstrate a fairly constant leukocytosis and the hemoglobin content and the specific gravity very little affected.

J. T. Dunn, (Closing): In regard to the method of entering the vein with the needle, of course that is largely a matter of personal equation. I made two or three jabs (as the patient called it) with the needle attached to the syringe and was not able to tell whether or not I had entered the vein. Upon making a little suction stroke I withdraw the needle a little ways, without entirely removing it from the skin, and make another attempt, with the same result. After making three or four unsuccessful attempts to enter the vein, I finally gave it up and administered that particular dose subcutaneously. Upon removing the needle I found that it was plugged up. I am sure that the needle was clean when I first introduced it, and I came to the conclusion that in making a suction stroke with the piston, some of the tissues had been drawn into the needle obstructing it, and it is possible that I entered the vein two or three times after that but failed to get any blood because of this obstruction in the needle. Thereafter I removed the needle from the syringe afterloading the syringe so that it was filled to the point of the needle, ready to be expressed. When the vein was entered the blood would flow into the cap of the detached needle, and when the cap was full I attached the syringe and had no trouble in forcing the blood back into the vein, followed by the phylacogen.

Answering Dr. VanZandt's question as to the type of cases in which phylacogen should be given, I will say that I should not hesitate to give it to any patient who had tried the various forms of treatment for rheumatism without permanent results.

APPENDECTOMY, FOLLOWED BY CROUPOUS PNEUMONIA; RE- COVERY.

(REPORT OF A CASE.)

By O. H. KELSALL, Louisville.

Patient, J. R., white, age 27.

PERSONAL HISTORY.

Had measles, parotitis and varicella in childhood. Had a severe case of typhoid fever at 17 years of age. Two years ago, last April, had a severe attack of articular rheumatism being confined to bed ten weeks. For several years past, he has had occasional attacks of abdominal cramps but never severe enough to compel him to quit work.

Patient first seen by the writer April 14th, 1912. He was found suffering with general abdominal cramps. No localized pain on pressure but with a rigidity of the right rectus so slight that the writer was in doubt about it. Temperature was normal. Further physical examination revealed a mitral regurgitant murmur at the apex, which was transmitted to the left. Lungs normal. The next day, April 15th, pain was localized over McBurney's point; rigidity of the right rectus marked but temperature only 99; pulse 76, and patient expressed himself as feeling much better. Notwithstanding this, operation was advised and accepted, the patient being operated on the same afternoon, i. e., April 15th. The appendix was found lying between the caecum and ileum and was removed without much trouble. It was gangrenous from base to tip. The abdomen was closed with a cigarette drain leading down to the stump. The patient got along very nicely for the first two days, having only slight elevation of temperature but a slight cough was noticed. On the third day, however, his cough became worse and his temperature went to 102. Physical examination revealed consolidation of the upper lobe of the right lung. In two or three days' time the patient also developed the rusty colored sputum that we generally see in croupous pneumonia. The patient began to improve after about seven days, the improvement taking place by lysis rather than by crisis. The writer supposes that this was due to the septic condition resulting from the appendix. His heart action, fortunately, remained good throughout.

An interesting question is, to what was this pneumonia due? Was it due to the ether, of which only 200 grammes were used administered by the drop method on the open cone, or was it a metastasis from the septic appendix?

The patient left the infirmary three and

one-half weeks following the operation and returned to work five weeks following the operation.

DISCUSSION.

M. Casper: I believe that many cases of so-called ether pneumonia may possibly be due to the infection already in the system rather than to the ether itself. In a case like the one reported, why could it not be due to both factors—that is, the sepsis already in the system and the irritation of the lung produced by the ether? I have had a good many cases of so-called ether pneumonia which may have been due to either cause. I do not believe that ether itself will cause pneumonia, and that in cases where the anesthetic is seemingly the only factor, it is due to the fact that some foreign substance has found its way into the lung. Furthermore, it is perfectly feasible that the infection may travel through the circulation, just as it does in the kidney. There is no reason why the lung should not be infected through the blood stream; in fact, it is perhaps more liable to it than any other organ, because the blood is "worked over," as it were, more in the lung than in any other organ in the body. Therefore, I believe that a good many cases of so-called ether pneumonia could be traced to systemic infection.

O. H. Kelsall, (Closing): There are several rather interesting points about this case. First, although the patient did not seem to be very ill, when we opened the abdomen we found the appendix gangrenous from base to tip. Second, notwithstanding a mitral regurgitant murmur, the patient survived the anesthetic, the operation and a croupous pneumonia. Third, that this patient should have developed a croupous pneumonia following the operation.

Influencing of the Opsonic Index by Drugs.—Strubell states that some of the common drugs have the effect of sending the index up or down; different drugs have a different influence in this respect according to the chemical composition of the drug, but no action could be detected from salt. Iodin and bromin salts are active in this respect as also urea. In his experiments the latter had a marked influence in reducing the opsonic immunity to staphylococci. This became apparent in fifteen minutes and reached its maximum in an hour. Arsenic, on the contrary, had an opposite effect, rapidly raising the index, in conformity to its therapeutic action.

SOME NOTES ON THE WORK OF MR.
ROBERT JONES IN LIVERPOOL.

By JOHN D. TRAWICH, Louisville.

The visiting doctor, who calls at No. 11 Nelson Street, Liverpool, sees Mr. Jones in his working clothes. He is impressed, first, with the tremendous energy of the man, and secondly, with the enormous amount of work he accomplishes. It is difficult to specify any one thing that he does better than another, but one of the conditions that he has had largest experience in correcting, is that of the internal semi-lunar cartilage. He very modestly states that up to the present, he has done "about eight hundred of these cases," but his house surgeons and those who are in most intimate contact with his daily work, state that his cases now number into the thousands.

His method of procedure is briefly as follows: With the patient brought well down on the table, so that the knee is flexed with the leg hanging down and the well side protected so as to be clear of the field, under strictest asepsis, he makes a crescentic incision, extending downward and forward from the lower border of the internal condyle of the femur. Laying aside the knife, with which the skin incision was made, he, with another, opens the synovial sac and, the cartilage, if loose as it generally is, will present at opening. Catching this with a strong grasping forceps, it is pulled out to its limit and cut off deep at its attachment. The incision into the capsule of the joint is closed with iodinated cat gut, then the deeper fascia, then the skin with silk-worm gut interrupted sutures, dipping the needle into pure iodine each time before entering the skin. After the incision is closed the wound is bathed in iodine and dressed aseptically.

Another procedure in which Mr. Jones excels, not only in technic, but in results, is in the transplantation of tendons for correction of the maiming that follows the paralysis of polio-myelitis. Take for instance his operation for the transplantation of the tendon of the tibialis anticus into the base of the fifth metatarsal. The incision begins well above the internal condyle along the tract of the tibial tendon and extends downward to the point of its attachment. The tendon is detached from its insertion in the cuneiform and base of first metatarsal. The detached end of the tendon with part of the periosteum of the cuneiform, is held with forceps until the procedure on the other side of the foot is completed. The next incision is made on the external lateral surface of the dorsum of the foot, extending downward from about opposite the external condyle to the side of the fifth metatarsal articulation. The head of this bone is fully exposed along the external

lateral aspect. An incision is made into the periosteum. By blunt dissection a tunnel is made to extend under the bridge of skin and fascia, between the two incisions. The purpose is to slip the tendon of the tibialis anticus through this tunnel in such a manner that there will be an easy slant to the tendon in its new position, being quite sure that there is no acute angle, around which the tendon may be forced to glide. The end of the tendon with a small portion of the periosteum and bone, removed along with the tendon when it was separated from its attachment, is now brought into the tunnel and downward along the external aspect and buried into the incision that has been made through the periosteum at base of the metatarsal. If by any chance the tendon should be too short to reach to this bone, perfect functional results can be obtained by making anchorage upon cuboid instead. Mr. Jones uses a small nail, which he drives through the end of the tendon into the body of the bone to re-enforce the attachment. The periosteum is sutured over the tendon and the incision is closed in the same general way as that given above. The foot is dressed with a right-angle splint. It is very interesting to see the results of this re-enforcement of the paralyzed group of muscles by transference of the power of the functioning muscle of the opposite group; so that what once has been an extensor may be converted into a flexor or vice versa. In like manner a pronator into a supinator. The biceps tendon can be utilized to re-enforce the quadriceps extensor by attachment laterally into the patellar tendon. The peronei and the tibialis anticus can be made to interchange function, depending upon the group which has suffered in the primary disease.

This operation suggests another, which Mr. Jones is very fond of doing, and is dependent upon the principle that rest is absolutely essential to a paralyzed muscle or group of muscles. The healthy innervated muscle is working over time and if an equation can be established between the healthy and paralyzed side the probability of the restoration of function to the diseased muscles, is greater. The procedure is that of the formation of a skin flap, for instance at the elbow joint, in order that the arm may be kept in flexion. In those cases, particularly of useless arms, resulting from infantile paralysis, if there is ever so slight power of flexion and extension in the fingers, Mr. Jones does not hesitate to give a good prognosis. The forearm is flexed strongly upon the arm and small marks are made upon the skin, so as to outline the extent of the proposed incision for denudation. Then the forearm is extended and supinated. The incision is made along the route outlined and the skin is removed over this diamond-

shaped area. Hemorrhage is checked by force-pressure, or by compresses, rarely is it necessary to ligate. The forearm is now flexed into the former position and the edges of the wound, upon the forearm, are sutured to the corresponding margin upon the arm; thus it will be seen that the forearm is held perpetually in a state of flexion and in a position where the greatest use can be made of the least motion. It is very encouraging to see these little frail members restored to extension and flexion within a few months, provided the destruction has not been too great. As extension of the forearm becomes more and more possible, the scar that has resulted from this operation will stretch until it is possible, when improvement has progressed to that point where the surgeon would feel justified in removing the artificial re-enforcement, to make an incision along the length of the scar and allow for extension of the forearm to the fullest degree.

In his treatment of spastic paraplegias, Mr. Jones lays great stress upon the mental condition of the child, since that, to a very large degree governs the prognosis. If the child is dull, morose, ill-tempered and lacking in mentality, so that education of the child will be impossible, then he advises that no operation be attempted, but if the child is thought capable of being taught and seems willing to learn, then he argues, with very good reason, that the sooner the child can be put upon his feet and taught to walk, the quicker will his mental condition improve.

One point of particular interest in some spastic cases, in which he got good results, was the very considerable adductor spasm that was present. This spasm is sometimes so great that when the child is lifted up off of the floor the limbs will be drawn across each other with a spasmodic contraction of the adductors, producing the characteristic "scissors deformity." If the child is made to stand, generally he stands on his toes with knees turned in and there will be a restless reaching out of one or both hands, the thumbs strongly flexed upon the palm and the fingers extended irregularly. Division of the adductors and the elongation of the tendo-Achilles are the two principal primary procedures. In treating the contracted Achilles tendon it is better to do an operation that will result in an elongation of the tendon, rather than simply to sever the tendon, for in the latter case the contraction of the calf muscles is so violent that the ends of the severed tendon will be too far separated for union ever to occur, resulting in a useless flail ankle joint. Instead then of doing a simple subcutaneous tenotomy Mr. Jones cuts down upon the tendon, goes through the sheath and brings up the tendon, which is sometimes enormously

hypertrophied. This, he divides, removing a section usually about 3-4-inch long. A strong doubled, chronicized cat-gut suture is passed through the ends, of the severed tendon, and tied so as to allow for just the amount of separation desired, between the cut surfaces. This procedure of tenotomy of tendo-Achilles has been mentioned first, although it is not to be made the first operation in the series necessary for correction of the deformity of the paraplegia. Before this is done it is necessary to proceed to the division of the adductors, near their origin. This is best done openly, that is, a subcutaneous tenotomy cannot be sufficient, a conclusion easily reached after one has seen the ill results following the incompleteness of the subcutaneous procedure.

Each adductor tendon is taken in turn, severed, and a section removed from the tendon, so as to allow a free wide gap between the severed ends, then the tendon sheaths are cut, so as to remove every possible tendency to a too early recurrence of the adductor spasm.

The child is placed in a double Thomas abduction splint with feet in right angle braces. Of course the question of the section of the nerve roots at the spinal cord enters here, but this note is too limited to allow for discussion now.

It might be interesting just at this point to mention some of the ill results that may follow and which the writer has seen succeeding the so-called "Lorenz reduction" of congenital hip. Mr. Jones has particularly called attention to a few of these points, viz: From the prolonged manipulation a haematoma results, which may easily undergo infection with abscess formation. Thrombosis of the femoral vein has been noted ossitis of the head and neck of the femur, with infection of the joint cavity. Lastly, is the not infrequent fact, the rarely reported occurrence of fracture, or epiphyseal separation either above, or fracture and separation at lower epiphysis, due to too violent manipulation.

It is not with the idea of discrediting the procedure, that these facts are here inserted, but to call attention to the truth, that these incidents do occur, and to urge wise, anatomically correct manipulation, tempered with a full consideration of the shock that invariably follows prolonged manipulation in these cases, which are very frequently below par in general nutrition.

No account of a visit to Mr. Jones is complete without speaking of the great work he is doing in his open air hospitals at Baschurch and Heswold. The latter is reached by a bracing motor ride of some ten miles, over wonderfully kept roads, until the party reaches the banks of the River Dee. In the distance one sees the blue hills of Wales.

The Royal Country Hospital is built upon a high hill overlooking the valley of the Dee, and the pure air that sweeps away from the Welsh hills is the tonic on which Mr. Jones depends so, to re-enforce his generally conservative attitude in his treatments. The visitor is struck at once by the appearance of the little patients, lying contentedly in the beds, there in the open-air wards.

It would take too much time to enumerate all the cases one sees in the rounds, or to mention even half the operations done in a day,—congenital talipes, in every variety, results in poliomyelitis, hip-joint cases, spinal lesions, tubercular bones and joints—all are there and seem to thrive and grow wonderfully well in the open air. Not strange that this genius of the children, can insist on deliberate conservatism in treatment of tuberculosis of bones and joints, when he has such co-operation of sunlight and good air.

IRIODIALYSIS.

(REPORT OF CASE.)

By ADOLPH O. PFINGST, Louisville.

I wish to report a case of iriodialysis, a traumatic separation of the periphery of the iris from its attachment. This condition is not infrequently seen by men doing work along special lines, but it may be interesting to some of you to see how the iris may be separated, at its periphery, from the ciliary body.

This young man was injured, about a week ago, by being struck in the eye with the blunt end of a whip. When I saw him, six or eight hours later, there was some blood in the anterior chamber, but I could readily detect the separation of the iris at its periphery on the temporal side.

Such injuries are not so very uncommon and, fortunately for the patient, are not serious, either as regards function or the loss of the eye. This patient has practically a double pupil. Usually the patient does not suffer any great inconvenience, although at times there is diplopia on one side. So far this man has not complained of this. His vision is now 20-50 and I believe it will return to normal after the cloudiness of the vitreous clears up.

DISCUSSION.

A. L. C. Percefull: What form of treatment do you use in these cases?

A. O. Pfingst: The natural tendency is to use atropin so as to dilate the pupil and get the iris over towards the periphery. However, there is no treatment that is satisfactory and the rupture will remain as it now presents itself.

COUNTY SOCIETY REPORTS

Barren—The Barren County Medical Society met in the office of Dr. Botts, Glasgow, July 9, 1912, with the following members present: Miller, Deppi, Jordna, Leech, Botts, Porter, McCreary, Froedge, Grinstead, Siddens, Ashury, Furgeson, Turner, Taylor, Honaker and Starr. Visitors, W. F. Boggess, H. N. Leavell and D. W. Willmoth, Louisville.

The society was called to order at 10 a. m., by A. T. Botts, president pro tem. The minutes of last meeting were read and approved.

There being no clinical cases present, Dr. Leech introduced the subject of "Appendicitis," which was discussed by Drs. Honaker, Miller, Porter, Leavell and others. The discussion was interesting, but grew perceptibly duller as the time grew near for our annual dinner at Murrell's Hotel. I must remark in passing that the dinner at this excellent hotel was fine, and that our members and visitors seemed to enjoy the occasion to the fullest extent.

At one o'clock p. m., **H. N. Leavell** began his clinical work in the county court room, where about twenty patients awaited him. These cases were examined and prescribed for, doctors and the laity taking equal interest in the discussion of the more interesting and important features of each case.

W. F. Boggess' "Health Talk" in the circuit court room was listened to by a large audience of ladies and gentlemen who gave close attention to the lecture from beginning to end. I may safely say that the speaker's pleasing style and earnest appeals for better sanitation made a profound impression on all who heard.

In response to calls from the audience Drs. Leavell and Willmoth came forward and delivered short and appropriate addresses after which the society adjourned to meet August 13th, 1912.

J. M. TAYLOR, Secretary.

McLean—The McLean County Medical Society met at the court house with the following doctors present: P. D. Moore, W. W. Spicer, J. W. Clarke, W. P. Miller, H. W. Gates, J. H. Thorpe, J. H. Thorpe, J. S. Fitzhugh and W. L. Haynes. J. H. Thorpe, president, presiding.

P. D. Moore was elected as a member, he having recently moved here from Ohio county.

On motion of **W. P. Miller** and seconded by **W. W. Spicer**, it was ordered that our dues be 50 cents annually to the county society.

J. H. Thorpe read a paper on "Hookworm" which was certainly very interesting and instructive. It was an excellent paper showing that he had made a close study of his subject. There have been no cases of hookworm in this county, hence we knew very little to discuss the paper.

J. S. Fitzhugh presented a paper on summer

diseases of children. This was well gotten up and showed the Doctor to be well prepared to handle this dread disease which carries so many little ones away. It was discussed by every member present. The society was well pleased to have had two such instructive papers.

The Secretary was instructed to write to our representatives in Congress that we are heartily in favor of the "Owen Bill." He was also instructed to write to the Attorney General regarding the collecting of the fees for the birth and death certificates. Our doctors have fully complied with the law but thus far have received nothing on the orders sent us.

Our next meeting will be held at Calhoun on September 9th, 1912.

W. L. HAYNES, Secretary.

Pendleton—The Pendleton County Medical Society met at the Day House in Falmouth, Wednesday, August 14th, 1912, with the following members present: A. L. Beckett, P. N. Blackerby, O. W. Brown, J. A. Caldwell, H. C. Clark, J. F. Daugherty, W. A. McKenney, John E. Wilson, J. Ed Wilson, K. B. Woolery.

A few clinical cases were reported

W. A. McKenney read a paper on "Nephritis," which was pretty generally discussed.

J. A. Caldwell read a paper on "Peritonitis," which was discussed by Ed Wilson and others.

We had a very good meeting.

W. A. McKENNEY, Secretary.

Warren—The regular monthly meeting of the Warren County Medical Society was called to order by the President, T. O. Helm, on Wednesday, August 21st, at 1 o'clock p. m., in the Doctors' Club Room in the City Hall. Fifteen members were present, viz: J. H. Blackburn, G. E. Huddle, H. P. Cartwright, F. D. Cartwright, Rogers, S. J. Martin, Freeman, Neal, M. M. Moss, E. Rau, B. S. Rutherford, E. N. Hall, W. P. Drake, T. W. Stone.

J. H. Blackburn made a very entertaining and instructive talk on "Pulmonary Embolism," citing several cases. Reported three cases caused from fracture of femur, other cases came after child birth, and operations on the pelvis. Little found in the literature on the subject. Fatty embolism usually occurs within three days of injury.

H. P. Cartwright discussed the subject in a very comprehensive manner, and emphasized how little had been written on the subject in the last ten or twelve years. Cautioned great care in the handling of fractures of the hip or femur lower down. Noted not be manipulated in effort to get crepetus.

J. L. Neal reported a case of "Pulmonary Embolism."

F. D. Cartwright, B. S. Rutherford and J. H. Blackburn forcibly discussed the paper.

T. O. Helm read a paper on "Anti-Typhoid In-

oculation," and brought out discussion of interest on the subject.

B. S. Rutherford opened the discussion, approving the treatment.

A motion was made and seconded to have the next regular monthly meeting at Chalybeate Springs. On vote motion carried.

E. RAU, Acting Secretary.

Warren—The July meeting of the Warren County Medical Society was held in Franklin with the Tri-County Medical Society. There was a splendid attendance and luncheon was served in the new hospital by Dr. Guthrie.

L. H. SOUTH, Secretary.

THE TRUTH ABOUT MEDICINES

TURNER OBESITY CURE.—Dr. Turner's Obesity Cure belongs in the same category as the Marjorie Hamilton "cure". Money is obtained from victims under the pretense that dieting, exercise and purging are not a part of the treatment. After obtaining the money the victim finds that he must follow a strict diet, that he must exercise and that he must take medicines, sold by the concern, particularly "Dr. Turner's Concentrated Food Tablets" and "Dr. Turner's Special Food Tablets" which, when examined in the Association's Chemical Laboratory, corresponded in composition to evaporated whey. Attempts are also made to wheedle the victims into purchasing a "To-Kalon Keapshape Corset" or a "Neal Reducing Belt." Dr. Turner whose name is used in connection with this obesity cure is also the manager of the Vanadium Chemical Company, which exploits various vanadium preparations to the medical profession.—*Jour. A. M. A.*, June 22, 1912, p. 1961.

LOOK WHOM YOU TRUST.—As a business house would scout a request to cash a check presented by an unknown individual, so physicians should refuse to pay attention to the claims made by firms of unknown standing. Still more should they refuse to pay heed to any preparations put out by a firm which has once been shown to be unreliable, as much as a commercial concern would quickly and positively refuse to cash the draft of one whose paper has been found to be worthless. These thoughts are suggested by an inquiry concerning the value of phytoline, put out by the Walker Pharmaceutical Company. A report of the A. M. A. Chemical Laboratory on hyoscyne (*Jour. A. M. A.*, June 11, 1910), exploited by the Walker Pharmaceutical Company, shows that this firm puts out nostrums of the worst class, namely, the kind whose composition is falsely declared and hence should receive no consideration.—*Jour. Mo. State Medical Association*

EDITORIAL

ENTERTAINMENT.

The arrangements for the entertainment of the members of the State Medical Association, at Louisville, have been so far completed as to enable us to make the following announcements:

Dr. Henry E. Tukey, Third and Broadway, Louisville, is Chairman, and Dr. A. C. L. Perceful, 835 South Fourth Avenue, Louisville, is Secretary of the Hotel and Information Committee, and either of them will be glad to give any information possible concerning the meeting and securing reservations at the hotels, and it is well to remember that the Hotel Watterson will be general headquarters and most of the members will stop there, but those who desire can secure quarters in private boarding houses, through either Dr. Tukey or Dr. Perceful.

A Committee composed of Drs. McMurtry, Morey and Hanes has arranged for a banquet to be given the visiting members by the local profession, at the Seelbach Hotel, on Wednesday night, October 30th, beginning at 7 o'clock. Visiting speakers, beautiful music, vocal and instrumental will, in addition to the viands which Dr. McMurtry and his Committee know so well how to order, beguile the time from 7 o'clock on until midnight. We feel sure that the members will never forget this banquet, which is to be given on a scale that has never been attempted before in Kentucky.

Drs. Frank, Wathen and Abell are acting as a Committee to arrange clinics for Monday, October 28th, and Friday and Saturday, November 1st and 2nd. These clinics will be held at the City Hospital from 8 o'clock until 12 o'clock in the morning, and in the after-

noon either at the Hospital or the college building, First and Chestnut, from two to five o'clock. A schedule of topics to be discussed is being rapidly arranged and will be published in the JEFFERSON COUNTY issue of the JOURNAL which will appear before the meeting. It will be of interest to the profession of the State to know that the doctors of Louisville have contributed more than \$1,500.00 for the entertainment of the State Society at this meeting. This is a small measure of the enthusiasm, cordiality and hospitality that will be extended to all of us by the splendid men who constitute the JEFFERSON COUNTY MEDICAL SOCIETY. It is up to the profession of the State to make such an adequate response as will show the Louisville doctors that we appreciate their efforts.

THE ANNUAL MEETING.

The Annual Meeting of the KENTUCKY STATE MEDICAL ASSOCIATION for 1912, will be held in Louisville, October 29, 30 and 31st. The first session of the House of Delegates will be on October 28th. The JEFFERSON COUNTY MEDICAL SOCIETY is united, active and aggressive in a way that it has never been before. Its officers and members are a unit in making such preparations for this meeting as will insure its success. They deserve and should receive the support of not only every county society but of the physicians and profession of the State in their efforts to break all records to make this the greatest medical meeting that has ever been held in Kentucky. It is especially important that every member who attends secure a certificate from his local ticket agent, when he purchases his railroad ticket, so that he can secure his return ticket for one-third fare.

The JOURNAL confidently promises every tired, hardworking physician who goes to Louisville such a hearty welcome and such a pleasant, profitable meeting that he will return home freshened up and stimulated for another year's work. This guarantee extends also to his wife, who more than in any other profession, shares the trials of the husband. Let's all get together and make the 1912 session the biggest and best yet held.

GET YOUR CERTIFICATE.

When you buy your ticket for Louisville, be sure to get a receipt from the local ticket agent on the certificate plan. It will entitle you to one-third fare in returning. If you fail to do this, you will have to pay full fare both ways as more than one-half of those who came to Paducah last year did.

BUSINESS.

This year again we publish in great detail reports of the ASSOCIATION'S officers, giving every item of expense and every step taken by them during the year. Have your resolutions, speeches and reports all ready for the House of Delegates. Ample time is given for any county society to instruct its delegates on any subject, and the delegate from every county society should confer with his fellows as to what should be done at the meeting. Every member is urged to read all the reports. It is your money being spent, your work being done, and if you are not familiar with all of its details, it is your fault not ours.

THE PROGRAM.

The program is again published in this issue. It is not quite complete but it promises enough good things to make it certain that no practicing physician can afford to miss it. We desire to call especial attention to the fact that the Committee on Scientific work has arranged for a full program for the third day; in fact, in many respects, the third day is the best of the three. Many of the papers will be illustrated by lantern slides and we will be able to see exactly what is being talked about.

THE DISCUSSIONS.

The KENTUCKY STATE MEDICAL ASSOCIATION is a democratic organization, where every man is his fellow's equal in opportunity anyway. If you are interested in any subject on this program and don't discuss it, it will be your own fault. When you have read the program, pick out the papers in which you are interested and write the Secretary at once. Every paper on the program is, or soon will be, in print. A proof will be sent any mem-

ber of any one paper. Then, will you, of your own experience and knowledge, deliberately and carefully, get up your discussions? Write it out if you prefer and hand it to the official stenographer just as you want it to appear in the JOURNAL. This plan worked well last year and will again this year, if the members like it. Write to-day for the paper you wish to discuss.

ORATIONS.

The annual oration will be delivered by the most forcible medical speaker in the South, Dr. John A. Witherspoon, President-Elect of the American Medical Association, of Nashville. Dr. Witherspoon is one of the most distinguished general practitioners of medicine in our country, and the message he bears will really be worth while.

Our orator in surgery, Dr. Arch H. Barkley, of Lexington, needs no introduction to the profession; that his address will be worth while, his work and worth guarantees.

Our orator in medicine, Dr. Curran Pope, of Louisville, has a manner and matter that will make his address noteworthy. You can't afford to miss either of these treats.

SCIENTIFIC EXHIBITS.

The scientific exhibits will be in the same rooms with the commercial exhibits. The Council has offered a premium of \$100.00 for the most instructive exhibit. Many good things are already promised. Eastern Kentucky will be strong with a line of special work on Pellagra. There is hardly a county in Kentucky, which has not had some cases of this disease. It may appear in your practice next. It will be worth your while to come to Louisville, if there were nothing else during the meeting but the scientific exhibit.

ONE HUNDRED DOLLAR PRIZE.

The Council desires to announce that \$100 in gold will be given for the scientific exhibit at the Louisville session, which will be most interesting and instructive for the general practitioner present. We trust some Kentucky doctor will arrange to get this prize.

COMMERCIAL EXHIBIT.

We will have the greatest commercial exhibit that has ever been in Kentucky. Only those firms can exhibit that are reputable and have something worth exhibiting. Instrument men, pharmacists and everything else of interest, including long distance telephone, will be on hand to show you the very latest. Save your orders until you can see what you want.

THE ASSOCIATION OF COUNTY SECRETARIES AND ASSOCIATE EDITORS.

The fourth annual meeting of the Association of County Secretaries will be held on Monday, October 28th, 7 to 9 P. M., at the Auditorium of the Jefferson County Medical Society, Atherton Building, Louisville, Kentucky.

The following program has been arranged and we urge that each county society arrange for their secretary to be present:

PROGRAM

Scope of Work of the Association, T. A. FRAZER, President, Marion.
The County Society, the Unit of Medical Organization, DELIA CALDWELL, Paducah.
Local Influence of the County Medical Society, A. C. L. PARCELT, Louisville.
Duties of the County Secretary, W. A. MCKENNEY, Falmouth.
How to Finance the County Society, J. J. ROEMAN, Owensboro.
The Value of Permanent Records of County Societies, F. A. STINE, Newport.
Need of Revision of Constitution and By-Laws, L. C. REDMAN, Lexington.
What is Expected of the Councilor in Maintaining County Organizations, C. Z. ARD, Cecilian.
Uniform Program for all County Societies, B. D. HANCOCK, Henderson.
Report of Committee of County Societies, Election of Officers.
Miscellaneous Business, T. A. FRAZER, Marion, President.
VERNON R. VITHE, Paducah, Vice Pres.
L. H. SOUTH, Bowling Green, Secretary.

IN APPRECIATION OF THE DOCTOR, WITH A WORD FOR THE OWEN BILL.

In this day of strenuous living of high prices and unpaid doctor's bills, the physician is apt to feel that he is neglected and is a failure. Of these, however, a word of encouragement from a grateful patient or a community, gives him new spirit to continue in his humanitarian work. The Century Magazine, in a recent issue, very kindly contributed a word of encouragement to the loyal doctor and we re-produce its tribute in full: "As one cannot draw an indictment against a community, so one cannot reasonably give sweeping approval of a profession; but now and then,—perhaps in the lifting shadow of some dread illness happily surmounted,—one is moved to a new sense of the obligations under which we all rest to the physician. Sometimes this is obscured by the conduct of those who "don the livery of heaven to serve the devil in"—a class against whom the profession wages persistent warfare; but on the whole not even "the cloth" presents a higher standard of service to humanity. Sordid and base, indeed, must be the man who can deliberately violate the solemn dedication of the Hippocratic oath, to which he must subscribe before he is accorded his degree:

I do solemnly swear by whatever I hold most sacred:

That I will be loyal to the profession of

medicine and just and generous to its members;

That I will lead my life and practice my art in uprightness and honor;

That into whatsoever house I shall enter, it shall be for the good of the sick to the utmost of my power, I holding myself far aloof from wrong, from corruption, from the tempting of others to vice;

That I will exercise my art solely for the cure of my patients and will give no drug, perform no operation for a criminal purpose even if solicited, far less suggest it;

That whatsoever I shall see or hear of the lives of men which is not fitting to be spoken, I will keep inviolably secret.

And there is need of this vow, if society is not to go to pieces, for little as we know of the physician, it is little of us that he does not know—our foibles and weaknesses, our sins and sorrows—and rare is the man or woman who is not debtor to his skill, his sympathy, his cheer, and his loyal devotion. It is always with a pang that we read of the death of such a doctor, trusting that he may have received in his last days some repayment in kind for all that he has given of service to others.

In the memory of many such experiences it is with indignation that one hears the rank and file of this noble profession pilloried as "the doctors' trust" by those opposed to the bill of Senator Owen for a National Department of Health. It is not necessary to probe for the motives of those who are fighting this admirable measure. Doubtless many, especially those of them who profess the faith of Christian Science, are conscientious, but nevertheless, under the banner of "medical freedom," they are playing into the hands of patent medicine manufacturers, adulterators of foods, and medical charlatans, to the peril of the public health. The Owen bill will merely extend to the whole country and make more effective the kind of sanitary guardianship which in the city of New York is accomplishing a progressive and astonishing reduction of the rate of mortality. Imagine for a moment the Department of Health of this city and port discontinued; it would not be forty-eight hours before we should be exposed to physical dangers comparable only to the brood of Pandora's box.

The fact is that in the practical application of preventive medicine American physicians are acknowledged to be the leaders of the world. They have not lost the primacy in this respect which twenty years ago led their confreres in Vienna to say: "We are astonished at your achievements; over here we wait with impatience for the publication of your volumes." Twenty-five years ago Mr. Bryce in his great book, "The American Commonwealth," quoted the appreciation of "com-

petent authorities" of our "contributions to biology and medical science." "Indeed, it is remarkable," he said, "how far from showy and sensational is the bulk of the work (in general science) now done in America." What must he say now of the great proportions which medical and surgical research have since attained! The pursuit of medicine in America fairly seethes with progress and interest. It has all the zest of exploration. Millions of dollars are invested in the study of diseases once thought incurable; unrelenting warfare is waged upon contagions, infections, and heredity; the education of the public on matters of health is systematic and thorough, and back of the professional honor which impels it all is a spirit of quiet altruism which is a better substitute for the knight-hood of the Middle Ages. Once more we say, gratitude and honor to the good physician!

HYDROPHOBIA OR RABIES.

The State Board of Health is glad to announce that it has been able to make arrangements with the Malford Company so it can secure the necessary preventable treatment by the Pasteur method, where persons are bitten by rabid animals so that the treatment may be given by the family physician. The necessary bacteriological preparation and complete outfit, including syringes and everything, will cost \$25.00. They can be supplied on the order of any health officer in the State.

Of course, it is to be understood that indigent cases will be continued to be treated, without expense, by the State Bacteriologist in the Laboratory at Bowling Green, and it is the desire of the Board that a liberal construction be placed on the term "indigent" in this connection. Where the patient is able to pay for the preventive treatment, however, there is no reason why it should not be given at home if his physician is prepared to administer it.

CONTAINERS.

Containers for bacteriological specimens are furnished free by the State Board of Health. It is against the United States Postal Laws to mail specimens in any containers except those supplied by the Laboratory. A number of physicians have been prosecuted and fined for mailing specimens in the wrong containers. We are publishing this so that our physicians may understand the matter. Any physician can get as many containers as he wants for any of the diseases for which examinations are made and they will not cost him one cent, so there is no excuse for any of our doctors being caught. Do not send in tuberculosis specimens in hookworm containers,

or vice versa. It will not be examined anyway as it does no good; besides, being a violation of the law.

MISSISSIPPI VALLEY.

We desire to call the special attention of the profession of Kentucky to the annual meeting of the Mississippi Valley Medical Association, which will be held this year in Chicago, with headquarters in the Hotel Sherman. The dates for the meeting are October 23rd and 24th. The program is an unusually good one in every respect but the profession of Kentucky will be chiefly interested in the meeting because it will be presided over by Dr. Louis Frank, one of the most popular surgeons in the State. It is especially important that the profession of Kentucky rally to Dr. Frank's support and help to make the 1912 meeting the biggest and best one this great Association has ever held. Be sure to remember the dates.

WELCOME HOME.

To all of ours members who have been wise and fortunate enough to take a summer vacation and have returned to their labors refreshed and rejuvenated, the JOURNAL extends a cordial welcome. This is especially and particularly extended to Dr. Joseph M. Mathews, who has received and merited all of the honors that could have been conferred upon him by the grateful medical profession of Kentucky, as well as by the entire profession of the United States. It is a pleasure and inspiration to have Dr. Mathews again in our midst and we are sure many of our members will attend the session in Louisville, gladdened by the prospect of again receiving a cordial welcome from this foremost of Kentucky physicians.

THE SHERLEY AMENDMENT TO THE NATIONAL FOOD AND DRUGS ACT.

Every physician in Kentucky should remember with gratitude Congressman Swager Sherley under the Fifth Kentucky District in which Louisville is situated for his action in securing the passage of amendment to the National Food and Drugs Act which practically puts the disreputable patent medicine vendors out of business. The amendment passed the House practically unanimously and was taken up in the Senate without being referred to a committee and passed unanimously. The JOURNAL extends its congratulations, not only to Congressman Sherley, but to the thousands of sick people who will be, in a measure, protected by this excellent law.

"AN ACT

TO AMEND SECTION EIGHT OF THE FOOD AND DRUG ACT APPROVED JUNE THIRTIETH, NINETEEN HUNDRED AND SIX.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That that part of section eight of the food and drugs Act of June thirtieth, nineteen hundred and six, defining what shall be misbranding in the case of drugs, be, and the same is hereby, amended by adding thereto a third paragraph to read as follows:

"If its package or label shall bear or contain any statement, design, or device regarding the curative or therapeutic effect of such article or any of the ingredients or substances contained therein, which is false or fraudulent."

So that the said part of said section eight shall read as follows:

"Sec. 8. That the term 'misbranded,' as used herein, shall apply to all drugs or articles of food or articles which enter into the composition of food, the package or label of which shall bear any statement, design, or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the State, Territory, or country in which it is manufactured or produced.

"That for the purposes of this Act an article shall also be deemed to be misbranded. In case of drugs:

"First. If it be an imitation of or offered for sale under the name of another article.

"Second. If the contents of the package as originally put up shall have been removed, in whole or in part, and other contents shall have been placed in such package, or if the package fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetaulide, or any derivative or preparation of any such substances contained therein.

"Third. If its package or label shall bear or contain any statement, design, or device regarding the curative or therapeutic effect of such article or any of the ingredients or substances contained therein, which is false and fraudulent."

OFFICIAL ANNOUNCEMENTS

PRELIMINARY PROGRAM OF GENERAL MEETING

OPENING SESSION--TUESDAY, 9 A. M.

Call to Order J. G. CARPENTER, M. D., President
Opening Prayer REV. E. L. POWELL, Louisville
Address of Welcome JOSEPH M. MATHEWS, M. D., Louisville
Response J. W. ELLIS, Masonville
Valedictory of Retiring President
Installation of the President
Report of the Committee on Arrangements,
By EDWARD SPEIDEL, M. D., Chairman, Louisville.

OFFICIAL CALL.

THE FIFTY-SEVENTH ANNUAL SESSION OF THE
 KENTUCKY STATE MEDICAL ASSOCIATION
 TO BE HELD IN LOUISVILLE, OCTOBER
 28, 29, 30, AND 31, 1912.

To the Officers and Members of the Component County Societies of the Kentucky State Medical Association:

The Fifty-Seventh Annual Session of the Kentucky State Medical Association will convene in the Auditorium of the First Christian (Dr. Powell's) Church, Louisville, Kentucky, on Tuesday, Wednesday and Thursday, October 29, 30 and 31st, 1912.

THE HOUSE OF DELEGATES.

The House of Delegates of the Kentucky State Medical Association will convene in the Auditorium of the Jefferson County Medical Society in the Atherton Building, at 1:30 P. M., on Monday, October 28th, 1912.

FIRST GENERAL SESSION.

The First General Session, which constitutes the opening exercises of the scientific functions of the Association, will be held in the Auditorium of the First Christian (Dr. Powell's) Church, Louisville, Kentucky, at 9 A. M., Tuesday, October 29th, 1912.

THE COUNCIL.

The Council will convene in a parlor of the Hotel Watterson, at 11 A. M., Monday, October 28th, 1912.

THE SECRETARIES OF COUNTY SOCIETIES.

The Association of Secretaries of County Societies will meet in the Auditorium of the Jefferson County Medical Society, in the Ath-

erton Building, at 7 to 9 P. M., Monday, October 28th, 1912.

THE REGISTRATION DEPARTMENT.

The Registration Department will be opened in the Exhibit Hall, on the main floor of the First Christian (Dr. Powell's) Church, from 10 A. M., to 7 P. M., on Monday, October 28th; from 8 A. M. to 7 P. M., Tuesday and Wednesday, October 29th and 30th, and from 8 A. M. to 11:30 P. M., on Thursday, October 31st.

APPORTIONMENT.

Each chartered component county society will be entitled to the number of delegates opposite its name on the following list. Each society is entitled to one delegate for each twenty-five members, or major fraction thereof, whose dues have been paid to the State Association in accordance with the By-Laws:

THE COMMERCIAL EXHIBIT AT LOUISVILLE.

The commercial exhibit at the Louisville session will have commodious quarters in the Assembly Hall of the First Christian Church; the scientific exhibit, the postoffice, the information bureau, the registration booths will occupy the same room.

Books, surgical instruments, diagnostic and therapeutic appliances, electric and X-ray apparatus, and many other specialties of practical value will be found in the exhibit hall. Well known pharmaceutical houses and manufacturers of therapeutic dietetic and biological specialties will be represented.

The Council offers the price of space used as a prize to the commercial exhibit which is of highest scientific and educational value to the general practitioner in attendance. There will be telephone booths in the exhibit room giving direct service throughout the building, to local telephone subscribers and for long distance.

In addition to the exhibits of firms mentioned below, valuable educational exhibits will be shown by the State Pharmaceutical Association, the Pure Food and Drug Bureau, United States Bureau of Animal Industry, the State Board of Health, consisting of the Bureau of Vital Statistics, the Bacteriological Laboratory, the Bureau of Sanitary Engineering, the Department for the Eradication of Hookworm.

Careful inspection of the exhibits is urged on every member in attendance.

W. B. SAUNDERS COMPANY.

W. B. Saunders Company, Philadelphia and London, will occupy space 28.

This well-known house will exhibit Murphy's "Surgical Clinics," Kelly's "Cyclopedia of American Medical Biography," Musser and Kelly's "Treatment," Cabot's "Differential Diagnosis," Hurst's "Obstetrics," [new (7th) edition], Stiles' "Nutritional Physiology," Daugherty's "Economic Zoology," Davis' "Operative Obstetrics," Mayo Clinic Papers, Moynihan's "Duodenal Ulcer" [new (2nd) edition], Anders and Boston's "Medical Diagnosis," Niles' "Pellagra," Kemp's "Stomach, Intestines and Pancreas," [new (2nd) edition], Pilcher's "Cystoscopy," "Fenger Memorial Volumes," Keen's "Surgery," Dorland's "Illustrated Dictionary," [new (6th) edition], Munford's "Surgery," Crandon and Ehrenfried's "Surgical After-Treatment," [new (2nd) edition], Seudder's "Tumors of the Jaws," also advance sheets of DeVee's "Obstetrics."

THE DE VILBISS MANUFACTURING COMPANY.

The DeVilbiss Manufacturing Co., of Toledo, Ohio, will have on display, Space No. 15,

at the Kentucky State Medical Meeting, to be held at Louisville, in October, a complete line of DeVilbiss Atomizers, Nebulizers and Powder Blowers; both for Physicians' office use and prescription purposes.

Members attending this meeting are invited to call at the DeVilbiss booth, which will be in charge of their representative, Mr. J. H. Nutt, who will be pleased to demonstrate the merits of the DeVilbiss line.

MUDLAVIA, KRAMER, INDIANA.

The institution that has popularized and perfected Mud Baths as a therapeutic agent in America will exhibit, by means of views and descriptive literature, the institution and treatment features. They will be represented by one of the Medical Staff. Space No. 5.

G. W. CARNRICK CO.

Messrs. G. W. Carnrick Co., manufacturing chemists and specialists in digestive ferment and internal secretion products, will exhibit at Booth No. 2.

Trypsogen. The enzyme and hormone treatment of diabetes mellitus which is based on the now accepted fact that diabetes is due to a deficient supply or absence of the internal secretion of the islands of Langerhans and that there is also absence or deficiency of trypsin and amyllopsin.

Trypsogen exerts a profound influence over nutrition. The first evidence of which is usually a marked increase in weight and strength, which is generally followed by definite improvement in urinary symptoms.

The value of Trypsogen in the treatment of diabetes and other wasting diseases of metabolism has been very thoroughly demonstrated during the past eight years until it is now recognized as the most dependable and successful treatment in these different conditions.

Secerogen contains the newly discovered hormone secretion which Baylis and Starling proved was the natural and in the case of the pancreas and liver the only stimulus which determines the discharge of their enzymes into the digestive tract just when they are needed and at the same time causes the building up of new ferment material.

According to Pavlov, enzymes as found in the digestive glands are incomparably superior to the strongest commercial extracts, hence where there is food stasis from deficient ferment action, resulting in fermentation and putrefaction, eructations, flatulence, etc., the most effective measure is the administration of Secerogen, which overcomes the condition by causing a profuse flow of the enzymes of the stomach, liver and pancreas.

Kinazyme the enzyme treatment of tuberculosis is founded on the work of Bayles and Joly of France with extract of spleen in the treatment of tuberculosis. In 150 cases treat-

ed by the former there were 75 per cent of cures, some at a very advanced stage. Joly records decided results in 93 per cent. of 83 cases.

Kinazyme is prepared from extract of spleen, trypsin, pancreatic extract and calcium lactate. It has given marked results in several hospitals and sanatoriums devoted to the treatment of tuberculosis.

SHARP AND SMITH.

Doctor: You are cordially invited to inspect our large display of instruments, comprising the latest and most improved patterns. Our representative Mr. E. F. Hutechraft will be in charge and will give you a useful souvenir of the occasion.

SHARP & SMITH,

Makers of High Grade Surgical Instruments, Hospital Equipment and Elastic Goods, Chicago, Illinois.

HORLICK'S MALTED MILK.

Mr. S. Z. Bryson will be in full charge of our exhibit, and as in former years will serve the famous Horlick's Malted Milk Ice Cream, and distribute samples of our product in both powder and tablet forms, also give out literature pertaining to the many uses of our product.

Horlick's Malted Milk consists of pure, full-cream milk, combined with the soluble extracts of choice malted grains, containing all the carbohydrates, protein and mineral salts needed to make a well-balanced food. As a food for infants and growing children it is unequaled, and thousands of infants have been raised to a healthy, happy and robust childhood by the use of our product, which is an endorsement in itself of the highest value.

HENRY K. WAMPOLE AND COMPANY.

Henry K. Wampole & Co., Inc., Philadelphia, Penn., exhibit a line of pharmaceutical preparations noteworthy for its elegance and typifying the highest standards in the work of the pharmacist. Fluidextracts, Elixirs, Syrups, Solutions, Pulverous Pills, Compressed and Hypodermic Tablets, Soft Elastic and Hard Gelatin Capsules are fittingly and attractively displayed, and impress the visitor with the exceptional facilities and careful methods which combine to give these products an eminent position in the class of pharmaceuticals. An exhibition which all in all will attract and impel your interest.

DR. H. M. ALEXANDER AND COMPANY.

At the coming meeting of your State Medical Association we will exhibit the different forms in which the several products of our Laboratories are marketed, including Smallpox Vaccine, Diphtheria Antitoxin, Tuberculin, Pasteur Antirabic Treatment and Silver

Nitrate Solution. Literature descriptive of these products will also be distributed.

TERRE HAUTE INHALATORIUM CABINET CO.

The Terre Haute Inhalatorium Cabinet Co., Terre Haute, Ind., Space 20, will contain an exhibit of the Inhalatorium manufactured by the company. All progressive physicians will be interested in this exhibit. The Inhalatorium is used in treating catarrh, hay fever, septic bronchitis following influenza, bronchitis, asthma, and pulmonary tuberculosis by means of volatilized medication.

DUNDEE WOOLEN MILLS.

The Dundee Woollen Mills will exhibit latest styles in suits, all made to measure. They wear a long time, fit well and are very, very stylish.

MELLIN'S FOOD COMPANY.

Mellin's Food Company will exhibit their product and give this year especial attention to the much discussed subject—Carbohydrates in Infant Feeding. Representatives of the Company will be in readiness to furnish visiting physicians the analysis of Mellin's Food, showing the relative amount of maltose and dextrin in their product, and offer much evidence to substantiate their claim that the carbohydrate content of Mellin's Food answer all the requirements for a sugar in infant Feeding.

CHAS. H. PHILLIPS CHEMICAL COMPANY.

The C. H. Phillips Chemical Co., New York, will exhibit:

1. *Milk of Magnesia*—a pure Hydroxide of Magnesia. "The perfect antacid" and milk modifier.

2. *Phosphomuriate of Quin. Comp.*—Condensed form of tonic solution and cell builder.

3. *Phillips' Emulsion of Cod Liver Oil.*—Fine as the fat in chyle—ready for assimilation.

4. *Digestible Cocoa.*—A nourishing, easily digested food—substitute for plain milk when latter is not liked or is tired of.

In addition to this we will show the relative neutralizing powers of the various alkalies as compared with "milk of magnesia," by the methylorange color reaction, and the action of artificial gastric juice on milk (at digestive temperature) modified by the various antacids used by the profession, including of course milk of magnesia.

MALTINA COMPANY.

The Maltine Company will be represented by Dr. J. S. Sullivan, who will direct the attention of the members especially to the Company's new preparation—Maltine with Olive Oil and Hypophosphites. He will be prepared to present to physicians not only specimens

of this preparation, but also of the Olive Oil which is used in its manufacture.

The Olive Oil used in Maltine with Olive Oil and Hypophosphites is the finest and purest oil procurable in Italy, where it is especially selected for and exported to The Maltine Company.

While the taste and odor of Cod-Liver Oil are very effectively masked in Maltine with Cod-Liver Oil, the fact remains that many persons have a prejudice, probably largely due to mental suggestion, to Cod-Liver Oil. During the last few years the medicinal value of Olive Oil has been demonstrated by many prominent physicians, and this bland vegetable oil is rapidly taking the place of Cod-Liver Oil with satisfactory and often brilliant results in cases in which the latter is not taken with ease.

THE JAECKH MANUFACTURING COMPANY.

The Jaeckh Manufacturing Company are the sole manufacturers of Dr. John Robertson's inventions and cordially invite you to inspect their exhibit of the Robertson Gold Metal Spraying and Nebulizing Outfit. The Improved Robertson Vacuum Cleaning Machine, tools and equipment. Compressed Air Sprayers, Air and Vacuum machines, all kinds of new atomizers, sprays, nebulizers.

D. APPLETON AND COMPANY, NEW YORK.

Will exhibit most recent medical books, published by them. A new eighth edition of Osler's Practice of Medicine, completely revised and printed from new plates, is just ready. Osler's monograph is offered in conjunction with Struppell's and Dieulafoy's Text-books in what is known as "the World's Great Practice of Medicine." Rachford's "Pediatrics," Guiteras' "Urology," Wood's "Pellagra," Walsh's "Psychotherapy," McCurdy's "Oral Surgery," and Gardner's "Gynecology," are some of the new works, while new editions include Kelly's "Medical Gynecology," Williams' "Obstetrics." Advance sheets of several important forthcoming books will be shown.

ABBOTT ALKALOIDAL COMPANY.

The special features of the exhibit of this company will be the demonstration of the methods of manufacturing granules of the active-principle and similar remedies by skilled laboratory workers, illustrating the hand methods. In addition this company will present a large line of alkaloidal and active-principle remedies, as they extract them from the drugs and in finished forms. Their interesting line of Council-passed specialties will also be demonstrated.

PITMAN-MYERS COMPANY.

The Pitman-Myers Company's exhibit will contain a number of preparations of U. S. P.

and N. F. formulas as well as some tablets and other preparations largely used by our members.

They are showing these preparations in special containers—glass tubes about five feet long—which permit a better display than if in bottles. It also makes the preparations more easily examined by those who visit the exhibit.

Mr. H. C. Moore, S. W. Ruch and J. R. McIntosh will be at the exhibit ready to meet their numerous friends among our members.

CUMBERLAND TELEPHONE AND TELEGRAPH CO.

The Cumberland Telephone and Telegraph Company will exhibit all the modern telephone and exchange system, they will have direct service throughout the building and will give special attention to long distance calls.

CONSTITUTION AND BY-LAWS OF THE KENTUCKY STATE MEDICAL ASSOCIATION ADOPTED AT PA. DUCAH IN 1902 AS AMENDED.

CONSTITUTION

ARTICLE I.—NAME OF THE ASSOCIATION.

The name and title of this organization shall be the Kentucky State Medical Association.

ARTICLE II.—PURPOSES OF THE ASSOCIATION.

The purpose of this Association shall be to federate and bring into one compact organization the entire medical profession of the State of Kentucky, and to unite with similar Associations in other States to form the American Medical Association, with a view to the extension of medical knowledge, and to the advancement of medical science; to the elevation of the standard of medical education, and to the enactment and enforcement of just medical laws; to the promotion of friendly intercourse among physicians, and to the guarding and fostering of their material interests; and to the enlightenment and direction of public opinion in regard to the great problems of state medicine, so that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of disease, and in prolonging and adding comfort to life.

ARTICLE III.—COMPONENT SOCIETIES.

Component Societies shall consist of those county medical societies which hold charters from this Association.

ARTICLE IV.—COMPOSITION OF THE ASSOCIATION.

Section 1. This Association shall consist of Members, Delegates and Guests.

Sec. 2. MEMBERS. The members of this Association shall be the members of the component county medical societies.

Sec. 3. DELEGATES. Delegates shall be those members who are elected in accordance with this Constitution and By-Laws to represent their respective component county societies in the House of Delegates of this Association.

Sec. 4. GUESTS. Any distinguished physician not a resident of this State may become a guest during any Annual Session upon invitation of the Association or its Council, and shall be accorded the privilege of participating in all of the scientific work of that Session.

ARTICLE V.—HOUSE OF DELEGATES.

The House of Delegates shall be the legislative and business body of the Association, and shall consist of (1), Delegates elected by the component county society, and (2), *ex-officio*, the officers of the Association as defined in Article VIII, Section 1, of this Constitution.

ARTICLE VI.—SECTIONS AND DISTRICT SOCIETIES.

The House of Delegates may provide for a division of the scientific work of the Association into appropriate Sections, and for the organization of such Councilor District Societies as will promote the best interests of the profession, such societies to be composed exclusively of members of component county societies.

ARTICLE VII.—SESSIONS AND MEETINGS.

Section 1. The Association shall hold an Annual Session, during which there shall be held daily not less than two General Meetings, which shall be open to all registered members, delegates and guests.

Sec. 2. The time and place for holding each Annual Session shall be fixed by the House of Delegates.

ARTICLE VIII.—OFFICERS.

Section 1. The officers of this Association shall be a President, three Vice-Presidents, a Secretary, a Treasurer, and eleven Councilors.

Sec. 2. The President and Vice-Presidents shall be elected for a term of one year. The Secretary, Treasurer and Councilors shall be elected for terms of five years each, the Councilors being divided into classes so that two shall be elected each year. All of these of-

ficers shall serve until their successors are elected and installed.

Sec. 3. The Officers of the Association shall be elected by the House of Delegates on the morning of the last day of the Annual Session, but no Delegate shall be eligible to any office named in the preceding section, except that of Councilor, and no person shall be elected to any such office who is not in attendance upon the Annual Session and who has not been a member of the Association for the past two years.

ARTICLE IX.—FUNDS AND EXPENSES.

Funds for meeting the expenses of the Association shall be arranged for by the House of Delegates by an equal per capita assessment upon each county society to be fixed by the House of Delegates, by voluntary contribution, and from the profits of its publications. Funds may be appropriated by the House of Delegates to defray the expenses of the Annual Sessions, for publication, and for such other purposes as will promote the welfare of the Association and profession.

ARTICLE X.—REFERENDUM.

The General Meeting of the Association may, by a two-thirds vote, order a general referendum upon any question pending before the House of Delegates, and the House of Delegates may, by a similar vote of its own members, or after a like vote of the General Meeting, submit any such question to the membership of the Association for a final vote; and if the persons voting shall comprise a majority of all the members, a majority of such vote shall determine the question, and be binding upon the House of Delegates.

ARTICLE XI.—THE SEAL.

The Association shall have a common Seal with power to break, change or renew the same at pleasure.

ARTICLE XII.—AMENDMENTS.

The House of Delegates may amend any article of this Constitution by a two-thirds vote of the delegates registered at that Annual Session, provided that such amendment shall have been presented in open meeting at the previous Annual Session and that it shall have been sent officially to each component county society at least two months before the session at which final action is to be taken.

BY-LAWS.**CHAPTER I.—MEMBERSHIP.**

Section 1. All members of the Component County Societies shall be privileged to attend all meetings and take part in all of the proceedings of the Annual Sessions, and shall be

eligible to any office within the gift of the Association.

Sec. 2. The name of a physician upon the properly certified roster of members, or list of delegates, of a chartered county society which has paid its annual assessment, shall be *prima facie* evidence of his right to register at the annual session in the respective bodies of this Association.

Sec. 3. No person who is under sentence of suspension or expulsion from any component society of this Association, or whose name has been dropped from its roll of members, shall be entitled to any of the rights or benefits of this Association, nor shall he be permitted to take part in any of its proceedings, until such time as he has been relieved of such disability.

Sec. 4. Each member in attendance at the Annual Session shall enter his name on the registration book, indicating the component society of which he is a member. When his right of membership has been verified by reference to the roster of the society, he shall receive a badge which shall be evidence of his right to all the privileges of membership at that session. No member or delegate shall take part in any of the proceedings of an annual session until he has complied with the provisions of this section.

CHAPTER II.—ANNUAL AND SPECIAL SESSIONS OF THE ASSOCIATION.

Section 1. The Association shall hold an annual session, meeting every third year in the city of Louisville, and the other two years at some point in the state fixed at the preceding annual session.

Sec. 2. Special sessions of either the Association or House of Delegates shall be called by the President at his discretion or upon petition of twenty delegates.

CHAPTER III.—GENERAL MEETING.

Section 1. The General Meetings shall include all registered members, delegates and guests, who shall have equal rights to participate in the proceedings and discussions; and, except guests, to vote on pending questions. Each General Meeting shall be presided over by the President, or in his absence or disability, or his request, by one of the Vice-Presidents. Before it, at such time and place as may have been arranged, shall be delivered the annual address of the President and the annual orations, and the entire time of the Session as far as may be shall be devoted to papers and discussions relating to scientific medicine.

Sec. 2. The General Meeting shall have authority to create committees or commissions for scientific investigations of special interest and importance to the profession and

public, and to receive and dispose of reports of the same; but any expense in connection therewith must first be approved by the House of Delegates.

Sec. 3. Except by special vote, the order of exercises, papers and discussions as set forth in the official program shall be followed from day to day until it has been completed.

Sec. 4. No address or paper before the Association, except those of the President and Orators, shall occupy more than twenty minutes in its delivery; and no member shall speak longer than five minutes, nor more than once on any subject.

Sec. 5. All papers read before the Society shall be its property. Each paper shall be deposited with the Secretary when read, and if this is not done it shall not be published.

CHAPTER IV.—HOUSE OF DELEGATES.

Section 1. The House of Delegates shall meet annually at the time and place of the Annual Session of the Association and shall so fix its hours of meeting as not to conflict with the first General Meeting of the Association, or with the meeting held for the address of the President and the annual orations, and so as to give delegates an opportunity to attend the other scientific proceedings and discussions so far as is consistent with their duties. But if the business interests of the Association and profession require, it may meet in advance or remain in session after the final adjournment of the General Meeting.

Sec. 2. Each component county society shall be entitled to send to the House of Delegates each year one delegate for every 25 members, and one for each major fraction thereof, but each county society holding a charter from this Association, which has made its annual report and paid its assessment as provided in this Constitution and By-laws, shall be entitled to one delegate. In case the regularly elected delegate is unable to attend the annual meeting of the Association, the President of the county society shall have the power to appoint an alternate, who shall have the rights and privileges of a delegate.

Sec. 3. A majority of the registered delegates shall constitute a quorum, and all of the meetings of the House of Delegates shall be open to members of the Association.

Sec. 4. It shall, through its officers, Advisory Council, and otherwise, give diligent attention to and foster the scientific work and spirit of Association, and shall constantly study and strive to make each annual session a stepping-stone to future ones of higher interest.

Sec. 5. It shall consider and advise as to the material interests of the profession, and

of the public in those important matters wherein it is dependent upon the profession, and shall use its influence to secure and enforce all proper medical and public-health legislation, and to diffuse popular information in relation thereto.

Sec. 6. It shall make careful inquiry into the condition of the profession of each county in the State, and shall have authority to adopt such methods as may be deemed most efficient for building up and increasing the interest in such county societies as already exist and for organizing the profession in counties where societies do not exist. It shall especially and systematically endeavor to promote friendly intercourse between physicians of the same locality and shall continue these efforts until every physician in every county of the State who can be made reputable has been brought under medical society influence.

Sec. 7. It shall encourage post-graduate work in medical centers as well as home study and research and shall endeavor to have the results of the same utilized and intelligently discussed in the county societies. With these ends in view, five years after the adoption of the By-Laws no voluntary paper shall be placed upon the annual program or be heard in the Association which has not first been heard in the county society of which the author is a member.

Sec. 8. It shall elect representatives to the House of Delegates of the American Medical Association in accordance with the Constitution and By-Laws of that body in such a manner that not more than one-half of the delegates shall be elected in any one year.

Sec. 9. It shall upon application provide and issue charters to county societies organized to conform to the spirit of the Constitution and By-Laws.

Sec. 10. In sparsely settled sections it shall have authority to organize the physicians of two or more counties to be designated by hyphenating the names of two or more counties so as to distinguish them from district and other classes of societies and these societies, when organized and chartered shall be entitled to all the privileges and representation provided herein for county societies, until such counties may be organized separately.

Sec. 11. It may divide the counties of the State into Councilor Districts, and, when the best interest of the Association and profession will be prompted thereby, organize in each district medical society, to meet midway between the Annual Sessions of the Association, and members of the chartered county societies, and none others, shall be members in such district societies. When so

organized from the President of such district societies shall be chosen the Vice Presidents of this Association, and the Presidents of the county societies of the district shall be the Vice-Presidents of such district societies.

Sec. 12. It shall have authority to appoint committees for special purposes from among members of the Association who are not members of the House of Delegates, and such committees may report to the House of Delegates in person, and may participate in the debate thereon.

Sec. 13. It shall approve all memorials and resolutions issued in the name of the Association before the same shall become effective.

Sec. 14. It shall present a summary of its proceedings to the last general meeting of each annual session, and shall publish the same in the Transactions or JOURNAL.

CHAPTER V.—ELECTION OF OFFICERS.

Section 1. All elections shall be by secret ballot, and a majority of the votes cast shall be necessary to elect, provided, however, that when there are more than two nominees, the nominee receiving the least number of votes on the first ballot shall be dropped and the balloting continue until an election occurs in like manner.

Sec. 2. Any member known to have directly or indirectly solicited votes for or sought any office within the gift of this Association shall be ineligible for any office for two years.

Sec. 3. The election of officers shall be the first order of business of the House of Delegates after the reading of the minutes on the morning of the last day of the General Session.

Sec. 4. Nominations for President shall be called for by counties.

CHAPTER VI.—DUTIES OF OFFICERS.

Section 1. The President shall preside at all meetings of the Association and of the House of Delegates; shall appoint all committees not otherwise provided for; shall deliver an annual address at such time as may be arranged; shall give a deciding vote in case of a tie, and shall perform such other duties as custom and parliamentary usage may require. He shall be the real head of the profession of the State during his term of office, and, so far as practicable, shall visit by appointment, the various sections of the State and assist the Councilors in building up the county societies, and in making their work more practical and useful.

Sec. 2. The Vice-Presidents shall assist the President in the discharge of his duties. In the event of his death, resignation or re-

moval, the Council shall elect one of the Vice-Presidents to succeed him.

Sec. 3. The Treasurer shall give bond for the trust imposed in him whenever the House of Delegates shall deem it requisite. He shall demand and receive all funds due the Association, together with the bequests and donations. He shall, under the direction of the House of Delegates, sell or lease any estate belonging to the Association, and execute the necessary papers; and shall, in general, subject to such direction, have the care and management of the fiscal affairs of the Association. He shall pay money out of the Treasury only on a written order of the President, countersigned by the Secretary; he shall subject his accounts to such examination as the House of Delegates may order, and he shall annually render an account of his doings and of the state of the funds in his hands.

Sec. 4. The Secretary, acting with the Committee on Scientific Work, shall prepare and issue the programs for and attend all meetings of the Association and of the House of Delegates, and he shall keep minutes of their respective proceedings in separate record books. He shall charge upon his books the assessments against each component county society at the end of the fiscal year; he shall collect and make proper credits for the same, and perform such other duties as may be assigned to him. He shall be custodian of all record books and papers belonging to the Association, except such as properly belong to the Treasurer and shall keep account of and promptly turn over to the Treasurer all funds of the Association which come into his hands. He shall provide for the registration of the members and delegates at the Annual Sessions. He shall keep a card-index register of all the legal practitioners of the State by counties, noting on each his status in relation to his county society, and upon request shall transmit a copy of this list to the American Medical Association for publication. In so far as it is in his power he shall use the printed matter, correspondence and influence of his office to aid the Councilors in the organization and improvement of the county societies and in the extension of the power and usefulness of this association. He shall conduct the official correspondence, notifying members of meetings, officers of their election, and committees of their appointment and duties. He shall act as Chairman of the Committees on Scientific Work. He shall be editor of the KENTUCKY MEDICAL JOURNAL. He shall employ such assistants as may be ordered by the Council or the House of Delegates. He shall annually make a report of his doings to the House of Delegates.

In order that the Secretary may be enabled

to give that amount of time to his duties which will permit of his becoming proficient, it is desirable that he shall receive some compensation. The amount of his salary shall be fixed by the House of Delegates.

CHAPTER VII.—COUNCIL.

Section 1. The Council shall hold daily meetings during the annual session of the Association and at such other times as necessity may require, subject to the call of the Chairman or on petition of three Councilors. It shall meet on the last day of the annual session of the Association for re-organization and for the outlining of the work for the ensuing year. At this meeting it shall elect a Chairman and Secretary and it shall keep a permanent record of its proceedings. It shall, through its Chairman, make an annual report of the House of Delegates at such time as may be provided, which report shall include an audit of the accounts of the Secretary and Treasurer and other agents of this Association, and shall also specify the character and cost of all the publications of the Association during the year, and the amount of all other property belonging to the Association under its control, with such suggestions as it may deem necessary. In the event of a vacancy in any office the Council may fill the same until the next annual election.

Sec. 2. Each Councilor shall be organizer, peacemaker and censor for his district. He shall visit each county in his district at least once a year for the purpose of organizing component societies where none exist, for inquiring into the condition of the profession, and for improving and increasing the zeal of the county societies and their members. He shall make an annual report of his doings, and of the condition of the profession of each county in his district to each annual session of the House of Delegates. The necessary traveling expenses incurred by such Councilor in the line of the duties herein imposed may be allowed by the House of Delegates upon a proper itemized statement, but this shall not be construed to include his expense in attending the annual session of the Association.

Sec. 3. Collectively the Council shall be the Board of Censors of the Association. It shall consider all questions involving the rights and standing of members, whether in relation to other members, to the component societies, or to this Association. All questions of an ethical nature brought before the House of Delegates or the General Meeting shall be referred to the Council without discussion. It shall hear and decide all questions of discipline affecting the conduct of members or of a county society, upon which an appeal is taken from the decision of an

individual Councilor. Its decision in all such cases shall be final.

Sec. 4. The Council shall have the right to communicate the views of the profession and of the Association in regard to health, sanitation and other important matters to the public and the lay press. Such communications shall be officially signed by the chairman and secretary of the Council, as such.

Sec. 5. The Council shall provide for and superintend the publication and distribution of all proceedings, transactions and memoirs of the Association, and shall have authority to appoint such assistants to the editor as it deems necessary. It shall manage and conduct the KENTUCKY MEDICAL JOURNAL, which is the organ of the Association, and all money paid to the Secretary as dues shall be received as subscriptions to the JOURNAL. All money received by the JOURNAL, the Councilor or any officer of the Association, shall be paid to the Treasurer of the Association on the first of each month.

Sec. 6. All reports on scientific subjects and all scientific discussions and papers heard before the Association shall be referred to the KENTUCKY MEDICAL JOURNAL for publication. The editor, with the consent of the Councilor for the District in which he resides may curtail or abstract papers or discussions, and the Council may return any paper to its author which it may not consider suitable for publication.

Sec. 7. All commercial exhibits during the annual session shall be within the control and direction of the Council.

CHAPTER VIII.—COMMITTEES.

Section 1. The standing committees shall be as follows:

A Committee on Scientific Work.

A Committee on Public Policy and Legislation.

A Committee on Medical Education.

A Medico-Legal Committee.

A Committee on Arrangements, and such other committees as may be necessary. Such committees shall be elected by the House of Delegates, unless otherwise provided.

Sec. 2. The Committee on Scientific Work shall consist of three members of which the President-elect shall be a member and Chairman, and the Secretary shall be a member and Secretary, and shall determine the character and scope of the scientific proceedings of the Association, or to the provisions of the instructions of the House of Delegates or of the Association, or to the provisions of the Constitution and By-Laws. Thirty days previous to each annual session it shall prepare and issue a program announcing the order in which papers, discussions and other business

shall be presented, which shall be adhered to by the Association as nearly as practicable.

Sec. 3. The Committee on Public Policy and Legislation shall consist of three members and the President and Secretary. Under the direction of the House of Delegates it shall represent the Association in securing and enforcing legislation in the interest of the public health and scientific medicine. It shall keep in touch with professional and public opinion, shall endeavor to shape legislation so as to secure the best results for the whole people, and shall utilize every organized influence in local, state and national affairs and elections. Its work shall be done with dignity becoming a great profession and with that wisdom which will make effective its work and influence. It shall have authority to be heard before the entire Association upon questions of great concern at such times as may be arranged during the annual session.

Sec. 4. The Committee of Arrangements shall consist of the component society in the territory in which the annual session is to be held. It shall, by committees of its own selection, provide suitable accommodations for the meeting-places of the Association and of the House of Delegates, and of their respective committees, and shall have general charge of all arrangements. Its Chairman shall report an outline of the arrangements to the Secretary for publication in the program, and shall make additional announcements during the session as occasion may require.

Sec. 5. The Medico-Legal Committee shall consist of three members, one of whom, the Chairman, shall be elected by the Council for five years, and the Secretary and the Treasurer shall be the other two members *ex officio*. This Committee shall select and fix the compensation for an attorney, who shall act as General Counsel, and, if required, additional local counsel. The Association through this Committee shall defend its members who are in good standing against unjust suits for malpractice.

CHAPTER IX.—ASSESSMENTS AND EXPENDITURES.

Section 1. The assessment of two dollars and fifty cents per capita on the membership of the component societies is hereby made the annual dues of this Association. The Secretary of each county society shall forward its assessment together with its roster of all officers and members, lists of delegates, and list of non-affiliated physicians of the county to the Secretary of this Association on the first day of January in each year.

Sec. 2. Any county society which fails to pay its assessment, or makes the reports re-

quired, on or before the first day of April in each year, shall be held as suspended, and none of its members or delegates shall be permitted to participate in any of the business or proceedings of the Association or of the House of Delegates until such requirements have been met.

Sec. 3. All motions or resolutions appropriating money, shall specify a definite amount, or so much thereof as may be necessary for the purpose indicated, and must be approved by the Council and House of Delegates on a call of the ayes and noes.

CHAPTER X.—RULES OF CONDUCT.

The principles set forth in the Principles of Ethics of the American Medical Association shall govern the conduct of members in their relations to each other and to the public.

CHAPTER XI.—RULES OF ORDER.

The deliberations of this Association shall be governed by parliamentary usage, as contained in Robert's Rules of Order, unless otherwise determined by a vote of its respective bodies.

CHAPTER XII.—COUNTY SOCIETIES.

Section 1. All county societies now in affiliation with the State Association or those that may hereafter be organized in this State, which have adopted principles of organization not in conflict with this Constitution and By-Laws, shall, upon application to the House of Delegates, receive a charter from and become a component part of this Association.

Sec. 2. As rapidly as can be done after the adoption of this Constitution and By-Laws, a medical society shall be organized in every county in the State in which no component society exists, and charters shall be issued thereto.

Sec. 3. Charters shall be issued only upon approval of the House of Delegates and shall be signed by the President and Secretary of this Association. The House of Delegates shall have authority to revoke the charter of any component county society whose actions are in conflict with the letter or spirit of this Constitution and By-Laws.

Sec. 4. Only one component medical society shall be chartered in any county. Where more than one county society exists, friendly overtures and concessions shall be made, with the aid of the Councilor for the District if necessary, and all of the members brought into one organization. In case of failure to unite, an appeal may be had to the Council, which shall decide what action shall be taken.

Sec. 5. Each county society shall judge of the qualification of its own members, but, as such societies are the only portals to this As-

sociation and to the American Medical Association, every reputable and legally registered physician who is practicing, or who will agree to practice, non-sectarian medicine shall be entitled to membership. Before a charter is issued to any county society, full and ample notice and opportunity shall be given to every such physician in the county to become a member.

Sec. 6. Any physician who may feel aggrieved by the action of the society of his county in refusing him membership, or in suspending or expelling him, shall have the right to appeal to the Council, which, upon a majority, may permit him to become a member of an adjacent county society.

Sec. 7. In hearing appeals the Council may admit oral or written evidence as in its judgment will best and most fairly present the facts, but in case of every appeal, both as a Board and as individual councilors in district and county work, efforts at conciliation and compromise shall precede all such hearings.

Sec. 8. When a member in good standing in a component society moves to another county in this State, his name, upon request shall be transferred without cost to the roster of the county society into whose jurisdiction he moves.

Sec. 9. A physician living on or near a county line may hold his membership in that county most convenient for him to attend, on permission of the society in whose jurisdiction he resides.

Sec. 10. Each county society shall have general direction of the affairs of the profession in the county, and its influence shall be constantly exerted for bettering the scientific, moral and material conditions of every physician in the county; and systematic efforts shall be made by each member, and by the society as a whole, to increase the membership until it embraces every qualified physician in the county.

Sec. 11. Frequent meetings shall be encouraged, and the most attractive programs arranged that are possible. The younger members shall be especially encouraged to do post-graduate and original research work, and to give the society the first benefit of such labors. Official position and other preferences shall be unstintingly given to such members.

Sec. 12. At the time for the annual election of officers each county society shall elect a delegate or delegates to represent it in the House of Delegates of this Association, in the proportion of one delegate to each twenty-five or major fraction thereof, and the secretary of the society shall send a list of such delegates to the Secretary of this Association at least sixty days before the annual session.

Sec. 13. The Secretary of each county so-

ciety shall keep a roster of its members, and a list of the non-affiliated registered physicians of the county, in which shall be shown the full name, address, college and date of graduation, date of license to practice in this State, and such other information as may be deemed necessary. He shall furnish an official report containing such information, upon blanks supplied him for the purpose, to the Secretary of this Association, on the first day of January of each year, or as soon thereafter as possible, and at the same time that the dues accruing from the annual assessment are sent in. In keeping such roster the Secretary shall note any changes in the personnel of the profession by death, or by removal to or from the county, and in making his annual report he shall be certain to account for every physician who has lived in the county during the year.

Sec. 14. The Secretary of each county society shall report to the KENTUCKY MEDICAL JOURNAL full minutes of each meeting and forward to it all scientific papers and discussions which the Society shall consider worthy of publication.

CHAPTER XIII. AMENDMENTS.

These By-Laws may be amended by any annual session by a two-thirds vote of all the delegates present at that session, after the amendment has laid upon the table for one day.

REPORT OF THE COUNCIL.

To the House of Delegates:

We have the honor of submitting the following report of the activities of the Council for the current year:

It is a matter of regret that the paid membership on September 1st does not show the usual increase. We feel confident that from the 400 physicians who are delinquent in their dues to their county society, more than enough will be collected before the meeting to overcome this. It is a pleasure to report the usual increase from our JOURNAL. Our JOURNAL income from advertising and other sources for the year has been \$5,910.56, as against \$5,385.00 last year. The actual expense of publishing the JOURNAL for the last fourteen months, 28 issues, amounted to \$7,014.00, making the net cost of the Journal for this time \$1,103.44. We feel a considerable pride in the fact that since October, 1906, during this time the JOURNAL has been under its present management, 318,060 JOURNALS have been actually mailed to the physicians of the State, at a net cost of \$303.95, including each and every cost of publication.

We feel that this is a cause for congratulation not only on account of the educational

and organization value of the JOURNAL to our members, but because it has demonstrated that a medical journal may be conducted honestly, and, at the same time profitably. From year to year, we have said that this remarkable showing cannot be continued without an even more active support of our advertisers in the future by the profession of the State. We are so confident, from careful investigation, that there is not a single firm among our advertisers which is not worthy of your patronage; that the Council stands ready to make good any money lost, occasioned by a mis-statement in any of our advertisements. We believe that this statement has never before been made by any medical or other publication. We accept no dishonest advertisements for our JOURNAL; and, after five years' experience, we feel confident that our methods have been perfected to the point where we will not be deceived, and we are willing to relieve our members of all risk in dealing with our advertisers for their advertised products.

If all of our membership will adopt a plan already in force in many societies of not only preferring those manufacturers and sanitarians which make their announcements through our own JOURNAL, but of calling the attention of all those who seek the patronage of the profession to that fact, we will have no difficulty in continuing to furnish our members with a satisfactory organ.

If we could receive help from two or three active members in each county, we could in a few years have sufficient reserve funds to undertake the protection of aged physicians, the establishment of an Old Doctors' Home, and such other things as have been the dreams of our profession.

The report of our Business Manager shows that 25 per cent. of the total membership of the Association have contributed to the columns of the JOURNAL through original or special articles, scientific editorials, the proceedings of our respective county societies or in some way. This condition is without parallel in any other state and shows that our JOURNAL is really representative of our two thousand members who not only own, but actually edit it. Since 1906, no article or other communication on any subject from one of our own members has been refused publication. During the coming year, our expense will naturally and necessarily increase if we continue this policy. We will appreciate such explicit directions as to the future conduct of the JOURNAL as your honorable body shall see fit to give.

At the meeting of the Council in Paducah during the 1911 session, the contract for printing the JOURNAL was let to the Times-Journal Publishing Company, Incorporated,

Bowling Green, for twelve months, on the following contract:

This contract made and entered into by the Kentucky State Medical Association, incorporated, party of the first part, and the Times-Journal Publishing Company, incorporated, party of the second part, witnesseth:

That the party of the second part hereby agrees to publish for party of the first part the KENTUCKY MEDICAL JOURNAL on the paper of the quality furnished, the body of the JOURNAL to be printed in 10 point DeVinne type, the discussions and similar matter to be in 8-point DeVinne type, not more than one-third of each issue to be advertising matter, set by hand, each Jefferson County issue to consist of 48 pages, 2,500 copies in consideration of the sum of \$160.00 per month; and each regular issue to consist of sixty-four pages, 2,500 copies, in consideration of the sum of \$200.00 per month, or eighty pages, 2,500 copies, in consideration of the sum of \$250.00, or of ninety-six pages, 2,500 copies, in consideration of \$350.00. It is further agreed that the party of the second part agrees that the JOURNAL shall be mailed to the members before midnight on the 26th day of the month preceding issue, subject to a penalty of ten dollars (\$10) for each twenty-four hours, or fraction thereof, delay.

It is further agreed that one-third of the copy of the Jefferson County number shall be in the hands of the printer on the 26th day of the month preceding issue, one-third on the 1st day of the month of issue, and the remainder one-third on the 5th day of the month of issue; the advertising forms close on the 1st day of the month of issue.

It is further agreed that one-third of the copy for the regular number shall be in the hands of the printer on the 5th day of the month before issue, one-third on the 10th and one-third on the 16th day of the month before issue.

It is further agreed that the copy shall be correct, and the party of the second part agrees to pay twenty-five (25) cents for each typographical error not contained in the copy, galley proofs and page proofs are to be submitted to the editor, and it is agreed that it shall be read and returned within twenty-four hours after its submission.

It is further agreed that the second party shall furnish envelopes, the return card to be printed on same at the rate of \$1.00 per thousand, which shall be addressed by the first party, and the JOURNAL shall be put in envelopes and mailed by the second party.

It is further agreed that this contract is to be continued for twelve (12) months, beginning this, December 1st, 1911.

Witnesseth our hands and seals this day and date above named.

KENTUCKY STATE MEDICAL ASSOCIATION (Inc.)

By E. RAY, Chairman Council.

TIMES-JOURNAL PUBLISHING COMPANY, (Inc.)

By W. J. DENHARDT, Manager.

It will be noted that this year, for the first time we have not been able to force our printers to pay for delays in publishing the JOURNAL. This has been because the copy from the Jefferson County number has been uniformly late during the year. Of course, we realize the difficulty of getting the copy always in on time, but we desire to suggest that, as long as it is worth some \$500.00 a year to the Association to do this, you take such steps as will be necessary to accomplish the purpose.

The contract with the Jefferson County Medical Society is as follows:

This contract made and entered into this first day of April, 1909, between the Jefferson County Medical Society, party of the first part, and the KENTUCKY STATE MEDICAL ASSOCIATION, incorporated, party of the second part, Witnesseth:

That in consideration of the securing advertising contracts in Jefferson County, Kentucky, by the party of the first part for the JOURNAL, published by the party of the second part, which shall provide for it a net income from said advertisements of \$2,400 per annum, the party of the second part agrees to publish on or about the fifteenth day of each month an edition of the said Journal which shall be known as the JEFFERSON COUNTY NUMBER, each issue to consist of forty-eight pages of reading matter and advertisements to be published and distributed under the following conditions, to-wit:

1. The Jefferson County Number of the KENTUCKY MEDICAL JOURNAL shall be published of the same style, size of pages, and shall be mailed to the same mailing list and shall be a part of the regular issue of the KENTUCKY MEDICAL JOURNAL.

2. Its editor and business manager shall be the same as for the KENTUCKY MEDICAL JOURNAL, but assistant editors and associate editors shall be nominated for it by the Jefferson County Medical Society from its membership, to the Council of the State Association.

3. The editorials for it shall be written by its own associate editors and the scientific editorials, by its own assistant editors, provided that editorial matter in regard to the public policy of the State Association shall be subject to the approval of the Council, as provided by the constitution.

4. Essays and discussions will be published in the order in which they are received from the secretary of the Jefferson County Medical Society.

5. The assistant and associate editors herein provided shall be assigned by the secretary of the Jefferson County Society to editorial work for the various issues at least three months in advance, and in case any such editor shall fail to send in his copy to the editor of the JOURNAL two successive times, the editor shall certify the fact to the Jefferson County Society, and another member shall be nominated to fill the vacancy thereby occasioned.

6. Advertisements of medical preparations shall be limited to U. S. P. and N. F. preparations, and to those approved by the Council on Pharmacy and Chemistry of the American Medical Association; of food preparations, to those which comply with the United States and Kentucky Pure Food and Drug Laws; and of sanitariums and business houses to those approved by the Executive Committee of the Jefferson County Medical Society; all advertisements being subject to the approval of the Council.

9. The business manager of the JOURNAL shall try as far as possible to secure advertisements for the Jefferson County Number, and the net income from such advertisements shall be credited in the consideration herein.

10. The Jefferson County Society may secure advertisements outside of Jefferson County, with the consent of the editor, the net proceeds to be credited two-thirds to the Jefferson County issue and one-third to the ordinary issue. The consent of the editor is required only to prevent competition between the two issues, and he shall in every way assist the Jefferson County Society in securing advertisements when they have a reasonable prospect of securing them.

11. Subscriptions to the KENTUCKY MEDICAL JOURNAL shall be at the rate of \$2.00 a year, and two-fifths of the income from subscribers secured by the Jefferson County Society shall be credited on the consideration herein, provided that such subscribers are not eligible to membership in the Kentucky State Medical Association, in which latter case, the whole subscription shall go to the general fund of the Association.

12. In case the total net income of the Jefferson County Number shall exceed \$2,400 per annum, sixty-six and two-thirds per cent. of the excess shall be paid to the treasurer of the Jefferson County Society, and thirty-three and one-third per cent. to the Kentucky State Medical Association.

13. The consideration herein is based on a forty-eight page issue, with a circulation not to exceed 3,000. For each additional 500 copies required the consideration will be increased \$25, and for each additional sixteen pages of any issue of 3,000 or less, it will be increased \$50.

14. While it is agreed that the Jefferson County Number is to be representative of and under control of the Jefferson County Society in so far as it does not conflict with the Constitution of the State Association, it is understood that the editor and the secretary of the Jefferson County Society may arrange for such interchange of articles between the two issues as will promote harmonious relations and united action between the parties heretofore at all times.

We have had the report of the Secretary and Treasurer audited by the Potter-Mattock Trust Company of Bowling Green, and submit their report herewith:

It will be noted again this year, as for the past five years, that each item of expense and income are set forth so plainly, that not only every county society and its Delegates, but every member of the Association, may know the details of our business affairs, which are of interest and importance to every one of us. This Council and your Officers will continue to work with the most careful attention to its every detail. It is to be remembered at all times that we are entirely under the control and direction of the members of the county societies through their duly elected delegates. If anything is being done wrong, if there is any way to improve it, if newer methods or better management will more nearly accomplish the purpose of this Association, we beg that it be submitted to the House of Delegates for its action at this session so that in the future conduct of the affairs of this Association we may best promote the purpose set forth in its Constitution and charter "to federate and bring into one compact organization the entire medical profession of the State of Kentucky, and to unite with similar associations in other states to form the American Medical Association with a view to the extension of medical knowledge, and to the advancement of medical science; to the elevation of the standard of medical education, and to the enactment and enforcement of just medical laws; to the promotion of friendly intercourse among physicians, and to the guarding and fostering of their material interests; and to the enlightenment and direction of public opinion in regard to the great problem of state medicine, so that the profession shall become more capable and honorable within itself, and more useful to the public in the prevention and cure of diseases, and in prolonging and adding comfort of life.

Respectfully submitted,

ERNEST RAU, Chairman.

AUDITOR'S REPORT.

Bowling Green, Ky., Sept. 26, 1912.

To the Council, Kentucky State Medical Association:—

GENTLEMEN:

We have the honor to submit herewith our report of the audit of the books and accounts of your Secretary, Dr. A. T. McCormack, and your Treasurer, Dr. W. B. McClure, beginning September 1, 1911, and ending September 1, 1912, viz:

ASSETS.

Cash balance in Second National Bank, Lexington, Kentucky, to the credit of W. B. McClure, Treasurer of Kentucky State Medical Association, as per pass book submitted	\$4,953 36
Office furniture, stationery and supplies, as per Exhibit "D"	1,216 96
Total Assets	\$6,170 32

Every item of disbursements was carefully scrutinized, compared and checked with the entries in the various ledger accounts. Each voucher contained an itemized statement of the account and was properly receipted. The cancelled vouchers in hands of the Treasurer agreed exactly with Secretary's stubs.

All amounts on Secretary's Cash Book from the various sources were found to agree with Treasurer's statement.

The exhibits herewith submitted furnish you a full statement in aggregate and detail the entire business of the year.

EXHIBIT "A"—RECEIPTS AND DISBURSEMENTS OF CASH OF YOUR ASSOCIATION, which includes Secretary and Treasurer, from September 1, 1911, to September 1, 1912.

EXHIBIT "B"—DETAILED STATEMENT OF DISBURSEMENTS OF W. B. MCCLURE, TREASURER, KENTUCKY STATE MEDICAL ASSOCIATION, each made on a voucher check, signed by J. G. Carpenter, President, A. T. McCormack, Secretary, and himself, from September 1, 1911, to September 1, 1912.

EXHIBIT "C"—DETAILED LIST RECEIPTS COUNTY SOCIETIES, from September 1, 1911, to September 1, 1912.

EXHIBIT "D"—INVOICE OF PROPERTY OF ASSOCIATION, September 1, 1912.

EXHIBIT "G"—SECRETARY'S MONTHLY BALANCE SHEET, agreeing with the books.

EXHIBIT "H"—COLLECTIONS BY EDITOR ON ACCOUNT OF KENTUCKY STATE MEDICAL JOURNAL, corresponding with checks for even amounts filed herewith.

EXHIBIT "I"—COLLECTIONS BY SECRETARY ON ACCOUNT OF KENTUCKY STATE MEDICAL ASSOCIATION, corresponding with checks for even amounts filed herewith.

We think it but right to state that in this audit, we failed to find a single omission, discrepancy or error in the books and records of either your Treasurer or Secretary.

Respectfully submitted,
POTTER-MATLOCK TRUST CO.

By B. P. EUBANK,
Public Accountant.

EXHIBIT "A."

Receipts and disbursements of cash, Kentucky State Medical Association, Bowling Green, Kentucky, September 1, 1911 to September 1, 1912:

REPORT OF THE SECRETARY.

I have the honor of submitting the following report from September 1, 1911 to September 1, 1912. The membership is practically the same as for the past two years. On September 1, we expect approximately 2,000 of our members to have paid their dues and to be in good standing. It is a matter of considerable regret that the entire membership of the Association does not pay their dues to the county secretaries on January 1st, of each year, as is done with fraternal and other similar organizations. I feel confident that greater promptness may be expected in the future as members not in good standing cannot, of course, be defended in case of malpractice suits. From the various counties, it is estimated that 400 physicians are, more or less, intimately connected with the Association, who do not appear on the roster at the time it is made up for the annual meeting. Many of these members fail to pay their dues to the county secretaries until immediately before the annual session. This not only keeps them off the official roster but keeps them from receiving the JOURNAL and keeping in touch with the actual work of the Association.

It will always be a matter of regret that a

larger number of members do not actively participate in the work, both of the county societies and of this Association. I am confident that the plan of organization is ideal, in many counties, in fact, is more than half of the counties of the State, practically, every physician worthy of the name is now actively at work. How may the organization then become more democratic? The only answer is that we must do more work for the benefit of the practicing physicians, who compose it, so as to secure their real interest and activity in the organization. The results that are being obtained possibly seem slow to some of our younger men, and yet the older ones can easily recall the many years before the re-organization when the total paid membership of this Association never exceeded 300, when there were practically no county societies and when there was no professional organization except along social lines. The annual meeting would have from 20 to 100 of the best and most successful physicians in the State and it is wonderful to us that they were able to accomplish anything when we understand that 3,600 of the 4,000 doctors then practicing in Kentucky, never knew there was a Kentucky State Medical Society and a large proportion of them never realized that they were members of a profession and owed it obligations as distinguished from their own individual work. The Jefferson County Medical Society has not only a larger membership than the entire Association used to have, but, under able and effective leadership, it has accomplished more in the past three years than the State Society did in its first forty years. Many of our county societies report a larger average attendance at their monthly meetings during the past year than the entire State used to have. In three counties, active campaigns for the betterment of health conditions of the people have been undertaken by the county societies and State Board of Health in cooperation. I wish every one of you could have been present in Knox or Bell or Edmonson counties at some of these meetings. If it had been necessary to pay for the services rendered by the organized profession in these three counties at the ordinary prices for such services, the entire income of this Association, in the 57 years of its existence, would be too small for the purpose and the resulting good to the profession and people of these three counties is incalculable.

There should be no let-up in the fight against those insurance companies whose examiners consist of only those members of our profession whose loss of self-respect or lack of attainment permit them to rate themselves as little better than half doctors. It is of special importance that we constantly keep in mind that the New York Life Insurance

Company is the only one of the so-called reputable companies which continues to insult the profession by offering a wholly inadequate fee for examinations. Examiners for such a company are a reproach to the profession but it must be constantly kept in mind that it is not because they charge so little for their services, for most of them are paid more than they are worth, if they are paid anything, but because their professional training was not such as to entitle them to the modest compensation demanded by the reputable and competent medical life insurance examiners. Of course, we all know that many medical students are not so grounded in Physical Diagnosis and the simpler laboratory methods necessary for insurance examiners as to make an examination by them of real value, and this Association should insist that its members should be properly equipped for service quite as earnestly as it did insist that they should be justly paid for them.

The campaign against the use of nostrums and for drug reform progresses slowly but surely. There can be no question that many lives have been sacrificed by the use of ready-made and hand-me-down pharmaceutical preparations of whose composition and indication manufacturers and prescriptionists, alike, are frequently entirely ignorant. This important matter cannot be discussed too frequently in county societies. Evidently no pharmaceutical combination should be prescribed unless its chemical composition has met the approval of the Council of Chemistry and Pharmacy of the American Medical Association, and it is to be regretted that many of the preparations they have approved are practically worthless, therapeutically. This campaign cannot be considered ended until our profession understands scientific chemistry and materia medica so they cannot be tempted to use the worthless drug messes now so frequent. Of course, the great majority of the reputable physicians of the State do not prescribe this class of mixtures, but it is to be regretted that a few men were so entirely untought in college in pharmacology and materia medica that they have been constantly the prey of the nostrum manufacturer since their graduation until now it is almost a mental impossibility for them to really understand either the physiologic or therapeutic indications for drugs. It is a pleasure to say that from careful personal investigation in twelve counties, I find that the profession is leading to that practical study of drug therapy, which is essential to our vocation—that of therapeutists. I have heard a large number of practicing physicians in various parts of the State express their disgust with consultants from the towns and

cities, who insisted on prescribing some pharmaceutical mixtures or food, about whose composition they knew nothing. It has been suggested that the family physician, in such cases,

write a firm but kind letter of protest to the consultant. This will be far more effective than criticising him to the patient or to other physicians.

I feel confident that the analysis of the usual membership tables will be found of special interest this year. It will be noted that the 1912 roll shows an increase over the five-year average in the first, second, sixth, seventh, eighth, tenth and eleventh districts, and decreases in the others. It is to be regretted that these ratios will be changed considerably as to the number of members who will pay their dues between September 1st

and date of the annual meeting. From the larger table, it will be seen that we have a population of 725 persons to each registered physician in the State. There are 1,393 registered physicians who are not members of this organization and, of these, 1,184 are eligible to membership. The special attention of the House of Delegates is again called to the fact that 424 of these non-members graduated since 1907. I desire to suggest that arrange-

ments be made with the faculty of the University of Louisville for a systematic course of lectures on Medical Economics and the advantages of society membership. This lecture-ship would be provided and conducted under the auspices of this Association. The medical profession and people of Kentucky have a right to be proud of the University of Louisville and we can show this best by active co-operation with them in the really excellent work they are doing. It is noteworthy that only 62 per cent. of the profession of Kentucky are members of their county societies. It is always difficult to draw invidious distinction, but I am sure it will be stimulating to the entire profession of the State to know that the largest proportionate membership is in the Eleventh District, where the physicians are very much scattered but where they are doing a character of work as an organization that makes it almost essential for every active doctor to be a member.

The attached tables show the average membership for five years compared with membership for 1912 with the increase or decrease as the case may be:

It will be noted that the total resources of the Association are \$6,377.30. The especial attention of the House of Delegates is called to the report of the Chairman of the Medico-Legal Committee, which leads us to fear an increased expense by this Committee in succeeding years.

PURE FOOD AND DRUG REPORT.

During the year 1911, the Food and Drug Division of Lexington inspected and analyzed 1,023 samples of drugs, 389 of which were adulterated. It also received and examined some several hundred labels and advertisements in connection with patent medicines. The drug analyses have covered a wide range of articles. The articles examined included aqua ammonia, arsenic iodide, asafoetida, aromatic spirit ammonia, ammonium carbonate, alcohol, acetic acid, ammonium bromide, acetanilid, acetphenetidin, aromatic sulphuric acids, boric acid, bay rum; bromide strontium, bismuth sub-nitrate, benzoic acid, borax, blue ointment, beef, wine and iron, chloral hydrate, spirit camphor, gum camphor, camphor liniment, chloride of lime, castor oil, cod liver oil, collodion, cream tartar, creosote, calomel tablets, citric acid, carbolic acid, calomel, dilute hydrochloric acid, dilute acetic acid, dilute phosphoric acid, extract witch hazel, extract nux vomica, essence lemon, epsom salts, Fowler's solution, glycerin, glacial acetic, hydrogen peroxide, iodine, iron and strychnine citrate, iodoform, lactic acid, lithium salicylate, lithium citrate, lime water, linseed oil, maganese sulphate, magnesium oxide, magnesium carbonate, mercurial ointment, morphine tablets, oxide zinc ointment, opium, oil peach kernel, oil

sweet almonds, olive oil, phosphoric acid, potassium carbonate, potassium cyanide, potassium citrate, potassium acetate, potassium bromide, potassium iodide, Paris green, paregoric, quinine sulphate, Rochelle salts, sodium bicarbonate, sodium carbonate, sodium bromide, sodium phenol sulphonate, silver nitrate, sugar of lead, strontium salicylate, sweet spirit nitre, spirit peppermint, sodium citrate, sodium salicylate, sulphur precipitated, sugar of milk, sodium phosphate, salol, solution ferric chloride, syrup ferrous iodide, salicylic acid, spirit ammonia, seidlitz powders, tincture iodine, tincture opium, turpentine, tincture ferric chloride, tartaric acid, tannic acid, tincture nux vomica, tincture ginger, zinc sulphate, zinc phenol sulphonate, zinc oxide. As in the case of the food analyses, each instance of adulteration and misbranding is being reported in the published notices and bulletins. This shows an examination of a wider list of articles than has been reported from either the Federal Government or any of the State departments.

The work for 1912 will include about as many or probably more samples and will include more constructive work than has been done heretofore. For example, in one instance, arrangements were made to co-operate with the druggists in the making of various standard tinctures, and in order to check up the accuracy of the ordinary pharmacists in this connection, amounts of standard ingredients were sent to various druggists over the State, who were asked to make the same into tinctures of iodine, sweet spirits of nitre, and so on, and to send the same in for analyses. The results showed that the Kentucky pharmacists can get pretty close to the standard laid down in the United States Pharmacopoeia, and show further that any shortages that may exist are due either to fault of the manufacturer or wholesaler, or to carelessness, and, in exceptional cases, fraud on the part of the retail druggists.

Work along the problem of the proper methods of preserving and protecting drug products from deterioration has been continued, and with evidence of splendid results.

The work against misstatements in the labels and advertisements of patent medicines is beginning to show results. For example, the label on Cascarets has been changed from "A Cure for Chronic Constipation," to "Intended for Use In Constipation." This last label, of course, accurately describes the properties of cascara, but the former label did not. Misstatements in many of the advertisements are still being made, but as the advertisements prepared for the year's consumption by the daily and weekly newspapers are appearing anew, much of the objectionable advertising is being eliminated; for example, the manu-

facturers of Duffy's Malt Whiskey stop saying that the product will "cure" various diseases, and "will make new blood," and so on.

The Division intends to take up the physiological assay of such products as digitalis, just as soon as the special food and drug laboratories that are being fitted up in the new building are available. The erection of the new addition to the Experiment Station will give laboratory facilities for food and drug investigation probably second to none in this country, and above all, will give facilities for greater increased work along all of these lines.

In conclusion I desire to record my especial appreciation of the active co-operation of practically all of our county secretaries in the routine work of the year, which has been carried on under your direction. Next to the Councilors, who are the *sine qua non* of our system, the county secretary is the most important link in the whole chain. To him fall the arduous duties of making and filling the programs and the society is a strong or a weak one in exact proportion to the value of the county secretary. To your officers, and to the whole membership, I desire to extend my gratitude for the assistance and courtesy which have made the arduous duties of my position unusually pleasant during the past year.

Respectfully submitted,

A. T. McCORMACK,
Secretary.

TREASURER'S REPORT

DR. E. RAU,

Chairman of the Council of Kentucky State Medical Association:

DEAR SIR:

For a detailed report of the transactions of the Treasurer's office I respectfully refer you to the published report of the Auditor in the October number of our JOURNAL.

You will observe from a perusal of the report (Auditor's) that compared with last year we are not quite so well off financially, and yet not a sufficient "shump" as to give rise to a panic.

We received from County Societies \$266.85 less in 1912 than in 1911.

But thanks to our Secretary through whose able intelligent and hustling qualities, we are enabled to report an increase of \$535.56 over last year's income from publication of the JOURNAL.

As we grow and do things more thoroughly than formerly our expenses naturally increase.

During the past year our disbursements have increased \$968.74 over those of last year.

With an expression of the belief that our Association is on a firmer basis, is doing bet-

ter work, and has a brighter future than ever before, I submit this brief report from the Treasurer's office.

Respectfully submitted,

W. B. McClure, Treasurer.

REPORT OF THE MEDICO-LEGAL COMMITTEE.

I have the honor to submit the following report of the Medico-Legal Committee. In making this my fourth annual report, I wish to again express my confidence in the value of the Medical Defense, and feel that the protection offered by this Committee is worth more in dollars and cents than any other feature of the State Association. The past year has been a very busy one, a total of thirteen cases having been presented to us. In 1909 five cases were reported, one went to trial, the rest were abandoned. In 1910 no cases were reported. In 1911 we had eleven cases, two were declined, one non-member, two trials were won, two cases are still pending, and four have practically been abandoned. In 1912 we have had thirteen cases reported, making a total of twenty-nine cases in the four years.

In the past few years several cases have been brought against non-members which were handled by other people and were not reported to the Medico-Legal Committee. This shows that suits are being brought against the doctors. The results of the Medical Defense is most gratifying. *So far we have not lost a single point.* This conforms to the results accomplished in other States. Out of several hundred cases occurring in the many States, so far, only two cases have been reported lost. One in New Jersey, and one in Illinois.

Of the thirteen cases which occurred this year, we refused to handle one case on the ground that the doctor resided in an adjoining State. It seems that in Eastern Tennessee many counties have no regular organized county societies and many of the doctors pay dues and are considered members of the Kentucky County Societies, and therefore are members of the State Society. Our Secretary informs me that the State of Tennessee gave its consent to these men to join the Kentucky county society. In view of the fact that he was a member in good standing in both the County and State Societies, our counsellor advised against supporting the doctor on the ground that he was a non-resident of Kentucky, and thought it a bad precedent to defend such cases.

One other case we refused to handle because the action occurred previous to March 15th, 1912, and the doctor joined his county society and paid his dues August 8th, 1912.

One case has been tried and won, one threat

has practically been abandoned, but at present we have nine cases pending and all look like trial cases, but we hope that many of them will be abandoned. In addition we have two suits pending from 1911, making a total of eleven cases pending at this time.

EXPENSE OF DEFENSE COMPARED TO OTHER STATES.

Massachusetts in four years had nine cases, with three trials, cost \$1,481.00.

Nebraska in four years had seven cases, no trials, cost \$278.45.

New York in five years had three hundred cases, with over two hundred won. Average cost \$3,000 per year.

Missouri in three years had forty-five cases, twenty-eight won or dismissed, cost \$1,100.

Iowa in four years had seventy cases, ten tried, cost \$10,051.35.

Illinois had nineteen cases in 1912, five tried, one lost, cost \$4,038.

Kentucky in four years had twenty-nine cases, four trials, cost \$1,861.15. (Total expense to date).

It might be asked, "What is the reason of the increase in the number of cases this year?" Other states report more cases in 1912 than in any other year. The most important factor in Kentucky might be explained on the ground that two or three cases succeeded in obtaining verdicts against the doctor. This is the experience in other states, where cases have been won other suits have been brought. This with the tendency to sue for damages in all industrial works prompts dissatisfied people to seek damages against the doctor.

I quote the following from the New York State report for 1912:

"The reason why a larger number of cases have been brought this year than for many years past, I cannot satisfactorily explain, except in one case, where it appears verdicts were secured against a dentist and a physician who was not a member of the State Medical Society, when soon thereafter there appeared in that particular locality five malpractice suits against members of the State Society; the increase in membership of the State Society does not in itself afford a sufficient number to account for this increase in suits brought. The willingness of members of the State Society and others to make use of what is known as indemnity insurance, is a potent factor in breeding malpractice cases. I believe that members of the profession should abandon this practice of taking out insurance; it might be thought to show moral weakness on the part of the profession, and is harmful not only to the man who is the holder of the policy, but to the profession as well."

Our relations with the insurance com-

panies have been pleasant; however, they are seeking a line of work which we are trying to check. I mention this question in our interest and not as a criticism of the various companies offering this line of insurance.

RECOMMENDATIONS.

1st. The funds to defend suits are obtained by one of two ways. First, from the funds of the State Society: Second, additional dues. Only states with a large number of doctors as New York, Massachusetts, etc., rely upon state dues alone. Other states collect from seventy-five cents to two dollars from each member for defense dues. Kentucky is the lowest, fifty cents, and to be able to meet the demand, which is very liable to occur by having on hand so many suits, which might have one or more trials; with the possibility of carrying the suit to the Court of Appeals, leads me to the opinion that we should increase our dues to one dollar per member.

2nd. We would especially advise the doctor to be guarded in handling all cases as the tendency to sue is becoming more common, especially, in fractures.

In fracture cases it is well to follow the example of a certain doctor. He always asks for a consultant. One patient said to him, "Why is it, Doctor, that you always ask for another doctor in these cases?" The doctor's reply was, "If things go wrong you would have a dozen lawyers."

On account of the frequency of suits for malpractice, our responsibility has increased and we should not hesitate to call a consultant or be watchful of all facts pertaining to treatment and management of these cases. *Let me remind you that all cases are not surgical, the general practitioner is suffering most.*

3rd. The question of counter claim suits for malpractice has given the Committee some work. It is the opinion of your chairman that some specifications should be made to govern these cases. The most essential is that these questionable bills against dissatisfied patients should be submitted to our attorney for advice before plunging into a suit for collection.

In 1911 through the advice of our attorney we stopped a suit of \$10,000 by the doctor agreeing to drop a bill of \$15.00 or \$20.00; however, I wish to say the doctor did his best and had the support of his associates.

It is hard to turn down a doctor who is sued, but it seems hard to defend cases that are prompted by threats of collecting bills against poor people who are dissatisfied. I do not wish it understood that I propose to let all bills be dropped, but I do want you to know some of the questions that confront us and ask your advice.

4th. Again I ask the physicians to be care-

ful of their remarks concerning the work of others.

Respectfully submitted,

JOHN J. MOREN,

Chairman, Medico-Legal Committee.

I have appended to this report a statement prepared by our attorneys, Hines & Norman, of all cases handled by your Committee since it was organized. This statement includes many cases of threatened suits which were never brought, the claims being dropped in some cases as the direct result of our efforts. The matter of fees of local counsel is a troublesome one as we have to act in some cases on such short notice that our general counsel have not time to negotiate with local counsel as to fees. If we could have an attorney retained in each county or district in the State the matter of attorneys' fees would be simplified, but since we regard the wishes of the defendant in the selection of local counsel as far as possible it is not feasible to have an attorney retained in all cases in each county. It is our aim to have the ablest attorneys we can employ in every case, and it always takes money to get the best, but we are learning by experience and believe that the doctors themselves can help us to keep down expenses. In one or more cases the defendant has indicated to attorneys in advance the fee that would be paid and has thus embarrassed us in our effort to agree upon a fee. The doctors can help us very much by letting attorneys know that the medical defense fund is a limited fund and that the medical defense branch of this society cannot continue to exist if we are to pay liberal fees to attorneys in every case, regardless of its merit. While we do not wish to be treated as charity clients yet we believe that when attorneys generally understand that malpractice suits are as a rule unjust and that our general counsel serve us for hardly more than nominal compensation they will recognize the propriety of charging fees which might be considered small in other damage suits. We trust, therefore, that our members as they have opportunity will help us to educate the legal profession along the line suggested. Counter-claims for damages in suits by doctors on their bills are also troublesome cases as to attorneys' fees. Such counter-claims are usually interposed merely to defeat the doctors' bill, and the doctors' attorney, if the doctor were paying the costs of the suit, would not think of charging such a fee as he would charge for defending an original suit against the doctor for malpractice, yet when this Committee steps in the attorney, in fixing his fee, is prone to treat the suit as an original suit for malpractice, and to charge accordingly. We believe that it would be wise for the Association to adopt a rule that in no event shall our Committee pay more than \$50.00 on

the attorney's fee in such cases. There can be little doubt that the doctor could hold down to that amount in most cases the additional fee charged by reason of the Counter-claim, and such a rule would make doctors cautious about suing on their bills where there is a prospect of a counter-claim for damages.

Your Committee would further report that our attorneys prepared and caused to be introduced at the last session of the Legislature a bill amending the statute of limitations as to malpractice suits so as to reduce the period of limitation from five years to one year, and the bill passed the Senate in the last days of the session but too late to be called up in the House. We are indebted to Senator Hite Huffaker and Lieutenant Governor McDermott for their interest in the bill in the Senate.

Claim against Dr. P.—Colles fracture and dislocation of wrist joint. Defendant reduced and set fracture and dislocation September 28, 1908. Defendant was ready for trial when plaintiff dismissed case December 7, 1909. Fee of \$100 paid.

Claim against Dr. H.—Mistake in giving creosote instead of harmless eye water for eye. Verdict for defendant May 25, 1911. Dangerous case. Attorney's fee of \$250.

Claim against Dr. M.—Setting of broken leg, October, 1910. Bad results alleged as result of defendant's negligence. Verdict for defendant, October 5, 1911. Attorney's fee \$100.

Claim against Dr. K.—Suit for Doctor's bill for treating fracture of the femur ulna and radius in March, 1910. Counter claim. Compromised in October, 1911, by Doctor remitting part of bill. Attorney's fee of \$100.

Claim against Drs. S. & S.—Removal in March, 1912, of particle from eye alleged to have resulted in loss of eye. Verdict for defendant in May, 1912. Trial occupied two days. Attorney's fee \$250.

Claim against Dr. C.—Mistake in prescription for glasses in June, 1909. Plaintiff required to give bond for costs, which she has failed to do. Case is sleeping.

Claim against Dr. B.—Colles' fracture of arm, December, 1910. Suit filed March 25, 1911. Will probably never be tried.

Claim against Dr. Me.—Operation on frontal sinus followed by delirium tremens resulting in death. Piece of instrument left in cavity. Answer filed and case will probably be tried in November.

Claim against Dr. H.—Nail wound in foot. Doctor said operation would have to be performed but parents of child said "Wait and see." and in defendant's absence had operation performed by another Doctor. Trial had September.

Claim against Dr. Mc.—Suit in Magistrate's Court for Doctor's bill of \$45 for setting

broken arm of child of ten years of age. Counter-claim for damages for alleged malpractice and case transferred to Circuit Court where it is pending. Probably reached for trial in November.

Claim against Dr. B.—Suit in Federal Court at Paducah. Amputation of leg. Motion to require plaintiff to elect whether he would sue Drs. B. and McW for the alleged negligent treatment prior to amputation or sue all the defendants for the alleged negligent amputation and he elected to sue all the defendants for the alleged negligent amputation. Case will probably be tried in November.

Claim against Dr. S.—Dislocation of left hip joint of boy of 13 years of age. Alleged that defendant negligently failed to replace the dislocated joint although he represented that he had done so. Treatment in April and May, 1911 and suit filed in July, 1912. Defendant took out policy in Medical Protective Company in September, 1911, but they refused to defend as policy was taken out after alleged act of malpractice.

Claim against Dr. C.—Injury to leg in falling of chestnut pole upon it causing two pieces of wood to enter the flesh. Alleged negligence in failing to remove the pieces of wood from the leg causing permanent lameness. Answer filed and case will probably be tried in November.

Claim against Dr. B.—Pad left in abdomen after removal of ovary, and stitches subsequently taken out and pad removed. Death followed. Case will probably be tried in the near future.

Claim against Dr. L.—Treated September 4, 1911, a 9-year old boy, for a fracture of the arm, near the elbow. Arm knit satisfactorily but a nerve that had been damaged did not regain its function. Suit filed August 23, 1912.

Claim against Dr. F.—Compound fracture of forearm and crushed bones of hand of boy. Dismissed case because father and mother refused to follow instructions. Suit brought in August, 1912.

Claim against Dr. B.—Alleged negligence of defendant as County Health Officer of Kenton County in failing to isolate small-pox patient. Assistance given by our general counsel to defendant's attorney in December, 1908. Judgment for defendant.

Claim against Dr. G.—Injury to leg. Alleged improper treatment resulting in permanent lameness. List of authorities furnished by our general counsel to attorney for defendant, and correspondence and advice in December, 1909.

Claim against Dr. O.—Suit for libel in returning alleged false birth certificate. Counsel retained by Committee in December, 1911, to

defend but we refused to defend when plaintiff amended petition and based action upon alleged oral statements of defendant. No attorney's fee or other expenses.

Claim against Dr. H.—Threatened suit for alleged neglect of obstetric case. Claim abandoned when our general counsel wrote claimant's attorney that claim would be resisted by our Committee. No attorney's fee.

Claim against Dr. K.—Threatened suit in March, 1909. Facial paralysis following operation for acute mastoiditis. Correspondence and advice. Claim abandoned.

Claim against Dr. B.—Threatened suit in August 1909, for giving strong and dangerous medicine to plaintiff's wife from which she died. Correspondence and advice, and application made for defense. Claim abandoned after being placed in attorney's hands. No attorney's fee.

Claim against Dr. V.—Operation alleged to have been performed without consent. Correspondence with attorneys for defendant and reference to authorities. Judgment against Dr. V., reversed by the Court of Appeals in June, 1912.

Claim against Dr. M., in March, 1911. Threatened suit never brought.

Claim against Dr. S.—Threatened suit for death alleged to have resulted from Doctor's action in giving dangerous medicine which was too strong for the patient. Claim abandoned after conference by our attorneys with claimant's attorney. No attorney's fee.

JOHN J. MOREN,
Chairman.

REPORT OF THE BUSINESS MANAGER.

As the JOURNAL is owned by the physicians of Kentucky, the following tabulation should be of special interest to every one of them, as it shows the comparative status of the JOURNAL for the last two years:

	1911	1912
Number of pages of reading matter	1,138	1,128
Number of Advertising pages	494	506
Special Articles	1	5
Official Announcements	118	46
Special Society Reports	6	3
Index	11	8
Book Reviews	45	36
Editorials	71	94
Scientific Editorials	35	51
Abstracts	111	90
Original Articles	281	320
Illustrations	39	26
Forms	5	8
News Items	0	116
Advertisers	153	116

HOW THE JOURNAL IS MAINTAINED.

By referring to the report of the Council it will be seen that, as was shown in my last report, the JOURNAL has been published in former years not only without one dollar of cost to members but at a small net profit, and it may be of interest to you to know that this is true of no other State Journal, but this is not quite true of the present year. This means

that the entire cost of printing, distribution, and expenses incident thereto, have been paid from funds received from advertisers, subscriptions and sale of Journals. Our chief income has been from our advertising pages, and this gratifying financial statement would not be possible but for the recognition by county societies and membership generally of their interest in the success of this feature of the JOURNAL. The rigid scrutiny by the Council of the character of all advertisements admitted to our pages, excluding everything not conforming to the requirements of the Council on Pharmacy of the American Medical Association, has given a confidence to the profession, naturally skeptical because so often misled by publications which ought to have been dependable, which, properly recognized and continued, ought to put its patronage upon a reliable basis. With such carefully selected and dependable advertisers, if the JOURNAL is in the future to be conducted without expense to the Association, it is important that the members read and give preference to what is offered in our advertising columns, making them still more attractive and profitable to every firm which can come up to the high standards set by the Council.

EXHIBITS.

An especially active campaign was made to secure the right class of exhibitors for this meeting. A brochure explaining the central location and attractiveness of this metropolitan city as a place of meeting, and containing the floor plan of the exhibit hall, price list and other desirable information, was mailed to leading manufacturing firms in every section of the United States. The result is an exhibit as will be shown by the full description found on another page of this issue, worthy of your consideration. It is urged, in the same reciprocal spirit asked for our advertisers, that members visit and go over these exhibits carefully, and give to the people who patronize and help support our enterprises a proper preference in making necessary purchases.

THE INDEX.

As in former years, the January number will be found to contain a complete index of editorials, original articles, proceedings of county societies, official announcements and book reviews, with a cross index showing the name of every physician who has contributed an original article, or appeared in the proceedings of his home society. This shows a total of 471 who have in some way taken part in professional work during the past year.

ASSOCIATION OF COUNTY SECRETARIES.

In an effort to co-ordinate the business affairs of the county societies, in so far as they relate to this department, the Association of

County Secretaries was organized in 1909, and since that year, instructive and profitable meetings have been held on the Monday evening preceeding each general session. Letters go out to all county secretaries urging the importance of attendance, and why and how such attendance will benefit them and the work in their respective societies, although there is little difficulty in getting those to come who have ever been present at the meetings.

HOW EACH COUNTY SOCIETY HAS HELPED THE JOURNAL.

As a matter of interest to the entire profession, the following is published to show, in a measure, what each county society did for the JOURNAL in 1911, and again in 1912:

At first glance this seems a most creditable exhibit, and is so in contrast with what is being done in other states, but, when compared with what remains to be done before our organization reaches the ideals set for it by our counselors and other leaders, which are entirely possible and practicable if each county society and member did the best that is in them, and, in doing so benefitted themselves even more than the organization itself, past and present conditions might be considered only as stepping stones to a far better and brighter future. Knowing the spirit that inspires these leaders, and that is in you, if it can be aroused to action, I appeal to every member of the organization in Kentucky for such cooperation with, and support of, the Council and other officers, and the JOURNAL, as will, year by year, bring us nearer to these ideals.

Very respectfully,

L. H. SOUTH.

ORIGINAL ARTICLES

TRACHOMA.*

By JOHN McMULLEN, M. D.,

PASSED ASSISTANT SURGEON U. S. PUBLIC

HEALTH AND MARINE HOSPITAL
SERVICE.

Trachoma is a contagious disease of the conjunctiva presenting granules or the so-called trachoma bodies, with more or less hypertrophy, chronic in its course, of unknown etiology, most resistant to treatment, prone to remissions and exacerbations and always followed by the stage of cicatrization. By reason of its communicability, chronicity of course and its often disastrous results, etc., trachoma is the most important of all the inflammatory diseases of the conjunctiva. In 1897 trachoma was classified by the Federal Govern-

ment as a dangerous contagious disease, and is now so certified under the Immigration Laws.

The disease is characterized by connective tissue hyperplasia, and proliferation of lymphoid cells. The follicles so formed tend to degenerate and become encapsulated by the newly formed connective tissue—newly formed blood vessels then penetrate these follicles. The result is a distension of these follicles with a certain amount of fluid—they push up through the conjunctiva, degenerate, break down, and we have the stage of extrusion which precedes and gradually causes the terminal condition we know as cicatricial eyelids—a condition which is caused by no other disease of the conjunctiva save trachoma.

The etiology of trachoma is still unknown. The so-called trachoma corpuscles or bodies (Halberstaedter von Prowaczek) have also been found in eyes free from any evidence of trachoma. They have also been found associated with gonococci (ophthalmia neonatorum) and also in the male and female urethra.

The return of Napoleon's soldiers to Europe from Egypt where they suffered extensively with a distressing form of ophthalmia, was thought to have been the means of disseminating trachoma, but the history of this disease would seem to be of more ancient origin and by some said to have been originally endemic in the Orient, from whence it was gradually brought to the Westward. We now know that trachoma is scattered throughout Europe. The disease prevails in Russia, Turkey, Italy, portions of Austria Hungary (Galicia) Finland, Holland, Greece and Ireland. A recent investigation, by passed Assistant Surgeon, T. Clark, of trachoma among the Indians on various reservations in Minnesota and also the miners of the iron ranges of that State, showed that trachoma was very prevalent among the former, and to some extent among the latter though to a much less extent.

Trachoma is certainly a contagious disease and the condition of the eyes of trachomatous patients, varying from merely defective vision to total blindness as a result of the disease, indicates that it is also dangerous, not to life, but certainly to the sense of sight by reason of its destructive effect upon the tissues of the eye—justifying the classification of this disease as "dangerous contagious".

Prior to 1897 trachoma was not so classified and undoubtedly many immigrants were landed here then suffering with this disease, and thus established foci of infection. The practice of evertng the eye-lids of all aliens now obtains at the various immigration stations. Experience shows that, in order to definitely ascertain whether or not trachoma

exists, it is necessary to inspect the retrotarsal fold by doubly everting the upper lid. The small glove buttoner is a very useful instrument in accomplishing this. Observers differ as to the commencement of trachoma. From my observation, during the past eight years in the medical examination of arriving aliens at New York and Baltimore, I am of the opinion that trachoma commences as an acute conjunctivitis. While this inflammatory condition may vary somewhat from the average acute conjunctivitis, it requires observation and treatment varying from several days to several weeks before a positive diagnosis can be made. This rule is followed in the medical examination of aliens and it is found that the ordinary catarrhal conjunctivitis will subside in a comparatively short time, while the trachomatous case will soon show the hypertrophy, and present the raspberry-like appearance so characteristic of acute trachoma. Also in old cases of trachoma, when exacerbation and relapses occur, the appearance is analogous to acute granulations and the true nature of the underlying trouble is only revealed upon the subsidence of the more acute symptoms.

Trachoma is essentially a chronic disease and the time from the stage of invasion to the terminal one of cicatrization, is usually one of years, quick cures are probably mistaken diagnoses. It is a common occurrence among arriving aliens to see large families where the parents and all the children are suffering from trachoma—including occasionally the babe in arms. The statement that the negro race is almost immune to trachoma is not borne out at Ellis Island, where a considerable number of negroes from the West Indies are annually found to be suffering from trachoma. One of the most marked and stubborn cases of trachoma that has been treated at Ellis Island Hospital was in a negro girl.

The diagnosis, prognosis, etc., of trachoma, is the most troublesome subject with which the medical examiner of aliens has to deal. The diagnosis of a well-marked case of trachoma presents no special difficulty to one at all familiar with this disease, but the borderland cases, those of long standing and quiescent at the time of examination or too acutely inflamed to classify are the difficult cases to decide. It must be remembered that when the diagnosis of trachoma is made in the case of an alien and he is so certified, he is also certified as having a dangerous contagious disease, which puts him within the provisions of the Immigration Law, thus making his deportation mandatory. This is a serious matter with the alien who has probably sold all his worldly goods to secure enough money to pay his way to America. It is therefore of the highest importance that

there be no mistake made by our medical officers in the diagnosis of this disease in immigrant aliens.

A mistake made in the diagnosis of this disease, by the general practitioner works no special hardship on the patient, but sometimes enables him to make a quick cure in his case of trachoma (1). As previously stated, the diagnosis of trachoma in the early or initial stage is difficult, if not impossible, in advance of some treatment. There is however an early thickening of the conjunctiva especially in the cul de sacs, which is already deeply congested, giving the appearance not unlike a raspberry. The ocular conjunctiva does not usually share in this intense congestion. The secretion at this stage of trachoma is watery or at most, muco purulent, and ordinary remedies have no effect. When, however, the more acute symptoms have somewhat subsided, granules are seen protruding through the hypertrophied conjunctiva, ptosis is present, and we have a case of trachoma, which will require treatment indefinitely. Follicular conjunctivitis resembles the granular form of trachoma, and is often difficult to differentiate from it. The follicles are arranged in rows, and present the appearance of small beads. Their distribution corresponds with the normal follicles of the conjunctiva. They cause very little trouble usually, and recover with no damage to the conjunctiva. A cure can usually be effected by expression with the Knapp forceps. The pavement-like epithelium of vernal catarrh, covered with a milky film, and characterized by excessive itching, burning and watering of the eyes, and coming on with the first warm days of Spring, will assist in the differential diagnosis.

Parinaud's conjunctivitis, somewhat rare, is said to simulate a severe trachoma, is ordinarily unilateral, effects the neighboring lymph glands and has marked constitutional symptoms.

It is most unfortunate that there are no microscopical findings to determine the diagnosis of this disease, as is the case in favus, etc., and we are yet compelled to rely upon the clinical evidence alone. We now see but few of the old and worst cases of the disease. "Egyptian ophthalmia" with its many complications compared with the number encountered some years ago among immigrants. This has resulted from the careful examination of all eyes upon arrival here and thereby causing the steamship companies to avoid embarking such cases as would result in deportations and fines,—especially the latter. It is stated that the steamship companies are rejecting in Europe for trachoma more than one hundred thousand applicants for passage each year. In spite of this there were twenty-five hundred aliens found to be suffering with

this disease, and were so certified, upon arrival during the fiscal year ended June 30th, 1911. There is, therefore, an accumulation of aliens in Europe who are not permitted to embark for this country, because of trachoma. Their friends and relatives who are already here, and are constantly arriving, are anxious to have these come also, and are making strenuous efforts to gain their admission even though it be to make the laws and regulations less strenuous in this respect. Trachoma is certainly a contagious disease, which is dangerous to the sense of sight, and imposes upon the victim an awful handicap. There should be no let up in its detection among arriving aliens and the deportation of those suffering with it. Unquestionably, this works hardships upon many of them, and sad cases are unfortunately not a few, but this is inevitable, and we should not permit this to work upon our sympathy to such an extent that we are blind to our duty to our own people. Because trachoma is already present in our country, is no argument in favor of increasing the amount of this inveterate and dangerous contagious disease. The plea is often made by relatives and friends that these unfortunate people be sent to our hospitals at their own expense, until cured, but they are usually not satisfied to remain there until a cure is apparently effected. In fact, it is difficult to say when a disease is actually eradicated which is so prone to relapse as is trachoma. The cases that can be counted as cured with reasonable certainty are those where the conjunctiva is entirely cicatricial, and presents a smooth glistening appearance. This terminal stage, however, is often effected only after years of treatment, and then there are the many troublesome sequelae which may make him a burden all the remainder of his life. One of the most difficult problems in connection with the certification of trachoma, under the Immigration Law, is to determine at what stage of the process of cicatrization to draw the line between contagious and non-contagious. While trachoma is excluded as a dangerous contagious disease under the law,—is not permitted to land—there seems to be comparatively little notice taken of it in the various states. By reason of the long duration of this disease, its resistance to treatment, etc., the method of dealing with those so afflicted, to prevent their spreading the infection is a perplexing problem. It is however, a responsibility which the states must finally undertake. It is peculiarly true of trachoma, that "an ounce of prevention, is worth a pound of cure." Trachoma should be declared conditionally quarantinable. Once a diagnosis is made of trachoma, the case should be put under treatment at home or in hospital. The patient should be informed of the nature and

the seriousness of his disease, and instructed as to the necessary precautions to take in order to prevent its spreading to others by means of towels, etc., and told that a cure will only be effected by his thoroughly co-operating with the physician. It should be made a reportable disease, and each case followed up closely for the purpose of instituting proper sanitary measures.

If an alien, in this country less than three years, has trachoma, which the examining physician is able to certify existed prior to his arrival here, such alien should be reported to the Federal authorities, with a view to deporting him to the country from whence he came. The schools should be carefully inspected and all eyelids everted in such manner that the retrotarsal fold is brought clearly into view. Those suffering from trachoma should be excluded from the schools. While general rules can be promulgated for the care and treatment of persons afflicted with trachoma and the prevention of its spread, these will necessarily vary to fit the conditions found in the community involved.

The operation of removing the tarsal cartilage of the upper lid with its overlying conjunctiva and retrotarsal fold, as outlined by Prof. Hieserath of Konigsburg, is now advocated in selected cases. It relieves to a great extent the distressing symptoms due to corneal involvement and hastens the terminal stage, according to its advocates. My experience with the results of this operation is limited, but it would seem that these cases should be seen a year or so after the operation to form a more intelligent opinion. Unfortunately there has been but little advance made in the medical treatment of trachoma.

ADDRESS OF WELCOME TO THE MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION, JUNE 4, 1912.

By Gov. WOODROW WILSON.
(OF NEW JERSEY).

Mr. President and members of the American Medical Association, ladies and gentlemen, I feel it a privilege, as representing the State of New Jersey, to welcome this great society to its session this year in Atlantic City.

A great many people come to Atlantic City on all sorts of errands, most of them not serious. (Laughter). The problems that Atlantic City is confronted by is that it is the refuge of the idle, and those who are idle are apt to adjourn the ordinary standards of their lives. (Laughter). But you are doubly welcome here, because you have not come as idlers but as those who study the more serious problems of our lives, both individually and nationally.

Atlantic City is used now to investigation. (Laughter). You have come as investigators, not to investigate Atlantic City, except for your intimate knowledge of the make-up, the physical make-up of all citizens of the community (laughter), and I feel in facing a great association like this that I am facing a body of men and women who have a particularly intimate connection with the life of the country, because you are very much more than physicians individually. You are very much more than the advisers of individuals with regard to the problems of health. You are the guardians of communities. You are the guardians of communities not only with regard to those general sanitary problems which are summed up under the head of sanitation and general hygiene, for example, but of a great many moral problems also. In our day the old story that the physical welfare of man is very closely knit with the moral is very true, and as man thinks so is he, a thing which comes very much nearer being a physical fact than is usually realized, because there is undoubtedly an air of morale in most of the problems that you have to deal with. At any rate, by way of preliminary determination and as counselors or individuals, you are the arbiters, to some degree, of the life of communities.

I have sometimes wished there might be some way of establishing an official connection between doctors and the State that has been found in the case of lawyers. Lawyers are officers of the court, and are subject to discipline as such. They hold in their hands the honor of obeying and carrying out the laws of the Commonwealth, and they are held amenable on that basis. It is on that basis that men are dealt with for contempt of court and lawyers are held to a code which has nothing to do with their knowledge of the law. Similarly, it seems to me, the doctor, by reason of the license he holds, is reputed to represent morality as well as the knowledge of the community. (Applause). And the most interesting part of the profession is this, that knowledge is not vital unless it goes hand in hand with honesty and sympathy. I believe you will agree with me that one of the things to be regretted in modern times is that we have been obliged to specialize our professions to so great a degree, because in proportion as the medical profession is specialized, for example, the old family physician disappears.

I remember going over in my memory a single year of my family life with my children when they were small and finding that I had called in consultation 13 different specialists. (Laughter). There was no ill luck in the 13, because it all came out very happily. But where I had summoned 13 specialists my father would have summoned 1 family physi-

cian. My father would not have got as good advice as I got, and yet I lived through it. (Laughter and applause). But every time he sent for his doctor he was sending for a personal friend. He was sending for a man who had his confidence in a peculiar degree. He was sending for a man who walked along the paths of life with him as a comrade and confident. There was something very vital, there was something very useful in that relationship, and although we have certainly yielded only to necessity, it is unfortunate that we should have been obliged to specialize so much as we have, and therefore it is necessary, it seems to me, if you will permit me to suggest it, that we re-generalize our sympathies. I remember saying once, when I was following out a certain occupation, that I understood the chief business of a university was to make young men as unlike their fathers as possible. I will hasten to explain that as I did on that occasion. I did not then, nor do I say that now, in disrespect to the fathers, but merely this: By the time a man was old enough to have a son in the university he became so immersed in a special occupation and narrowed to the point of a single calling, it was advisable that his son should be taken out of some place of vantage where he could see the world, instead of seeing a single individual, a single community, a single profession. I understood that to be the business of the university to re-generalize each generation of youngsters, show them the Nation, show them the great infinite variety of human interests, show them the map of the world, so that they would never forget, at any rate, their general geographic relations to the races of mankind. So, it seems to me, every profession, particularly a profession so absorbed as yours is, and bent upon investigations, must find it necessary to refresh its general sympathies by re-connecting itself with the wider questions of our modern life.

As an American I feel that the task of a statesman in our day is analogous to the task of the surgeon. There is a great deal that is necessary to be cut out of modern life (laughter), and yet we must be very careful not to injure any of the sound tissue in cutting it out, and the various processes of politics are not unlike the processes with which you are familiar. The preliminary agitations of a political campaign are a sort of prognosis (laughter) and the platforms are a sort of diagnosis, and then follows the critical part. (Laughter). Then you have to study your *materia medica*; then you have to propose a particular operation and determine exactly what you are going to do in following up your diagnosis to remove the disease, or, at any rate, to apply some tonic which will enable nature to assist herself. (Laughter).

The moral of that sort of thing is that the surgeon should know what he is about, and that rough and ready methods, methods of passion, methods of prejudice, are of all things the most dangerous. (Applause). They are the methods of the quack; they are the methods of the uneducated, the uninstructed, the unlicensed practitioner, and therefore I have a sort of sympathy with you. (Laughter). It is very much easier for you to get at the difficulty and the particular phenomenon with which you have to deal than it is for the men who are wandering abroad amidst the general phenomena of society; and yet, it seems to me, that you can be infinitely instrumental in assisting the statesmen, because there are a great many evidences and symptoms at this time of hysteria (laughter), and if you will only hurry home from this convention and calm your communities down we may be able to transact business. (Roars of laughter).

I am very glad to have you all at once in New Jersey, but you can not calm New Jersey down by merely sitting here in Atlantic City. It will be necessary for you to disperse to your homes and get to work on the people you know. I know a great many people whom I would like to get to work on (laughter) if I only knew the proper cure for hysteria, but never having, happily, felt the symptoms myself, I am unsympathetic about it. And yet, seriously, ladies and gentlemen, speaking of the problems of our life, they are all one. The thing I am particularly impatient with, ladies and gentlemen, is dividing our lives and our interests into sections and supposing you know nothing about anything, except one thing. The whole problem of modern society is infinitely complicated, just because it is variously specialized, and it should be our object to avoid the separation of interests; it should be our object to effect a union of purpose, to unite ourselves with one another, not as a body of competing interests, but a body of unified interests, moving forward to the common goal of general service. That, it seems to me, is the problem of all intelligent men in the United States and in the world at large. I can not do better, therefore, than to ask you in your modern occupation to harmonize the various parts of our whole life to one another, so that heat, hostility, and friction may be taken out and all the sweet and wholesome processes of life may be restored. (Long and prolonged applause.)

PELLAGRA.*

By N. W. Moore, Cynthiaana.

In presenting a paper to this society on pellagra, I sincerely realize that my knowledge of this subject is a very limited one indeed; however, in this respect, I feel that I am not alone; but, if I succeed in creating sufficient interest in this so-called new disease, (or at least new to this country) enabling us to so qualify ourselves as to be able to diagnose a case of pellagra when coming under our care, I shall be more than satisfied, for I am sure we are liable to be confronted with a case of this kind most any day. Furthermore, I fully believe that if there was a competent medical house to house inspection, that we would find one or more cases in every county in the State of Kentucky. It has already been estimated that our State contains at least 3,000 cases, and that Georgia has the enormous number of 50,000. Our insane institutions are being over-crowded with these patients. Over 4,000 cases are now confined in the insane asylums of our southern states. Cases have been reported from thirty-two states and the number is constantly on the increase. Is this not enough to arouse every conscientious physician to "be up and ready" to meet this enemy?

Last summer when I stood by the bedside of a severe case of pellagra in the Lexington asylum and saw the patient motionless, paralyzed, insensible, dead to all the senses of the living, insane, emaciated to a mere skeleton, half-closed eyes, protruding tongue, inability to swallow, even water, which she so gravely having to be fed with a stomach tube; inflamed, ulcerated, cracked, bleeding arms and legs as if she had recently been withdrawn from a fiery furnace, and an involuntary diarrhoea and urine which had baffled all treatment, I asked myself into what lower state or condition could a human being fall? And woe to the physician who could look on such a sight and not yearn to know more about this horrible disease; and then I imagined that instead of prolonging the lives of these poor afflicted mortals, as they were doing, how much more humane would it seem if we were permitted by law to chloroform them into a sleep that knows no awakening; but should there be such a law, who among us would be willing to take upon himself such a responsibility, knowing too well that a disease considered incurable to-day may be a curable one to-morrow?

A few weeks ago, I had another occasion to visit the asylum and inquired of Dr. Dunlap as to the final outcome of the fourteen cases which I saw last summer, and also of the twen-

*Read before the Pendleton County Medical Society.

ty-six cases which I did not see, and she replied that "nearly all had died during the fall and that the few remaining mild cases had improved during cold weather." No photographs of these patients could be obtained, as I was informed that none had been taken, nor had there been any post-mortems made owing to objections from friends and relatives.

Pellagra has been known in Italy for over two hundred years, but was not recognized in the United States until within the last four or five years, though, no doubt, the disease has existed in some of our southern states for many years.

DEFINITION.

Pellagra is a complex disease, characterized by three classes of symptoms: First, an erythema confined to those portions of the skin exposed to the action of heat and light. Second, a chronic inflammatory condition of the digestive passages, shown chiefly by obstinate diarrhoea. Third, a more or less severe lesion of the nervous system, terminating in insanity and paralysis. These various symptoms are at first insignificant and in a certain way periodic, that is, they begin or occur in spring or early autumn and diminish or disappear in winter. Later they become persistent, more and more severe, and finally terminate fatally.

ETIOLOGY.

The cause of pellagra is still clouded in mystery. A great many authors claim that it is produced by eating decomposed corn meal. There are others equally as prominent who absolutely deny this mode of infection, saying that "it is due to some other bacteria ferment." A few claim that it is due to a specific microorganism called "strepto-bacillus pellagra" or some protozoa infection, very similar to that of ergotism. Even cotton-seed oil, and the sand-fly have been accused of producing this disease. It is possible and I am inclined to this belief that food cereals, and especially decomposed seed or infected corn meal has a great deal to do with pellagra. One experimenter, Dr. Bass, of New Orleans, has succeeded in producing all the symptoms of pellagra in the chicken and horse by feeding decomposed corn. Among the predisposing causes may be mentioned deficient alimentation, and bad hygiene. In those parts of Italy where the disease is endemic or prevalent, the poorer classes, especially the peasantry, suffer extreme privation as to lodging and food. During a considerable portion of the year their chief food consists of a heavy, sour, indigestible bread made from more or less spoiled grain. A similar diet prevails in most all other European countries where pellagra is endemic. That privation alone is not

sufficient to cause pellagra, is shown by the fact that in Ireland, where extreme poverty has at times prevailed, pellagra is unknown.

In an investigation throughout the entire state of Tennessee, ninety-seven per cent. of cases had used corn meal in some form or other, while the greater number of the patients were surrounded by poverty and bad hygiene, a few cases appeared in the well-to-do families with excellent hygienic surroundings. In this respect, we have an illustration in the death of the wife of a prominent physician of Lexington, Ky. It has been said she contracted the disease while visiting in the south. Females are more susceptible to the disease, at least seventy-five per cent. more than males. Infants at the breast have been known to contract the disease although it has not been proven that the mother's milk was the source of infection.

Physicians and nurses who have attended great numbers of pellagra cases have never been known to contract the disease, nor has there been one authentic case where contagion has taken place by coming in contact with the patient.

Is there a racial immunity to pellagra? Dr. Bernard Wolf, of Atlanta, Ga., claims that the Jews are immune. Out of thousands of cases he had seen within the last few years not a single case occurred in the Hebrews. It is a well known fact that the Jews are not eaters of corn bread, nor do they use other articles of diet that are under suspicion. On the other hand, the negro race does not possess any marked immunity.

PATHOLOGY.

Contrary to expectations, post-mortems have thrown no light on the cause of this disease, although there has been found fatty and atrophic changes in the heart muscles, brown atrophy and fatty degeneration of the liver, cirrhosis of the kidney, and intestinal ulceration. The most frequent and prominent of these morbid conditions are symmetrical sclerosis of the posterior columns of the cord. In quite a number of cases, exostosis of the vertebra has been found. Pressure from these bony growths upon the roots of the spinal nerves no doubt produce the excruciating pains in the limbs of which so many of these patients complain, while sclerosis of the posterior columns of the spinal cord may account for the symmetrical eruption which occurs in all typical cases. This discoloration also shows in the internal organs.

SYMPTOMS.

The symptoms being so numerous and so complex we shall only attempt to mention a few of the more important ones and for convenience, we have divided them into three

classes: First, the digestive symptoms; second, the skin manifestations, and third, the nervous symptoms.

Digestive symptoms are common in pellagra, mild at first, they become more and more marked, and consist of dyspepsia, heat and burning in the stomach and oesophagus, loss of appetite, and an uncontrollable thirst, cracking and fissuring of the lips, a fungus condition of the gums, a reddened aphthous condition of the buccal mucous membrane, and a dry cracked condition of the tongue which is enlarged and devoid of membrane, the so-called "bald tongue." In severe cases saliva flows continuously from the mouth, and the salivary glands are enlarged, resembling very much the appearance of mercurial salivation. The digestive disorders are sooner or later accompanied by diarrhoea which usually precedes the eruption by weeks or months. The stools vary in number from three to thirty in twenty-four hours, and frequently contain blood. The diarrhoea is at its maximum of intensity when the eruption is at its maximum and gradually improves after June or July.

THE SKIN ERUPTIONS.

This appears first in the early spring months and is one of the most characteristic features of the disease, as it is usually an index to the severity of the infection. The eruption commences as a severe sunburn on the back of the hands and neck and in those who go barefooted it may occur on the feet and legs; as the disease progresses it may be seen on the face and on those parts of the body protected by the clothing such as the knees and elbows. Rarely does it occur on the palms and planter surfaces. The erythema is a bright redness of the skin accompanied by itching and burning sensations. There may be papules, vesicles and fissures and when desquamation takes place the skin takes on that typical "goose flesh" appearance. Those of you who were fortunate enough to see those cases confined in the asylum last summer will remember how vividly this condition was demonstrated. After a time the skin desquamates and when the redness fades, the skin assumes a characteristic light liver or chocolate color, which if once seen can not be mistaken for any other skin disease. In mild cases the skin remains healthy until the following spring when the eruption reappears and follows the same course as it did the previous year, except that it is apt to be more severe. In some cases, the eruption remains throughout the winter, but it is not so severe as in the spring.

NERVOUS SYMPTOMS.

Mental depression goes hand in hand with the erythema and diarrhoea and varies from

a mild case of "blues" to severe melancholia. As one author expresses it "The patients seem to have forgotten how to laugh." The poor sufferers imagine they have not a friend on earth; that even their own children or parents dislike them and are devising some means to do them an injury; and under such delusions may commit suicide. Vertigo, tremors, partial paralysis, staggering gait, sometimes resembling locomotor ataxia symptoms, but in pellagra we have at first an exaggerated reflex. As the nervous centers become more and more affected we have almost complete paralysis. In the final stage of this disease the patient falls into what is called "typhoid pellagra" with extreme emaciation, fever, unconsciousness, involuntary defecation and urine, sordies on the teeth, inability to swallow food or water, and unless fed by the stomach tube or rectal alimentation, starvation ends the scene.

DIAGNOSIS.

Some authors claim that it is impossible to make a diagnosis unless we have the skin eruption. In pronounced cases, a diagnosis can generally be made from the triad of skin eruption, gastro-intestinal and nervous symptoms. From a thorough perusal of the history of this mysterious disease I am inclined to believe that we have very mild types—so mild that it is frequently overlooked, e. g., cases without any manifestations of skin lesions. It is probable that every physician in this section of the country has encountered just such cases and have treated them for some other malady, in a suggestive way. "Spring fever," or to use Hood's expression "that tired feeling" may possibly come under this category.

PROGNOSIS.

In Italy the mortality does not exceed ten per cent. but in the United States the mortality has been very high, thirty-five to sixty-five per cent. This high death rate is probably due to the fact that only the well-marked or severe cases have been recognized in this country. In Louisiana and Mississippi, where the mild type exists the mortality does not exceed that of Italy. If a recurrence of the symptoms do not take place within twelve months or longer there is little danger of the return of the disease, provided impure food and bad surroundings have been avoided during the time. Whenever the "knee-jerks" are exaggerated as they are in all moderate and early cases, indicating irritative nerve tissue, it is possible for the patient to recover; on the other hand, if the reflexes are entirely abolished the prognosis is not very promising. All of the "pellagra typhosus" cases die, some cases within a year from the onset, while others may live for many years. The usual duration is about three years.

TREATMENT.

Up to a few years ago, pellagra, like tuberculosis, was considered incurable. This opinion still holds good when applied to the far-advanced cases, but it can not be sustained when it comes to the treatment of the milder cases, even a few of the severe cases have been reported as cured. Arsenic in some form or others seems to be the only drug worth mentioning, although quinine, iron and calcium sulphide are highly recommended by some. The administration of salvarsan, as well as that of caedylate of sodium and Fowler's solution have brought about many cures. This alone is sufficient proof to me that pellagra is a germ infection; if not why such brilliant results from arsenic which we know to be so fatal to all kinds of germs? Improve the hygienic conditions, and surroundings, pure air and good nutritious food. Keep the patient out of the sunlight and have the room darkened and cool; if possible make the room cool with refrigerators, as nothing affects pellagra so favorably as cold. This fact is substantiated from the great improvement during the cold season. A certain physician in Georgia, whose name I cannot recall, has been sending some of his patients to Colorado and reports wonderful improvement so long as they remained in that climate. Our extreme northern states, or Canada, might prove more beneficial. In the treatment of the nervous symptoms, I should think that the bromides would be contraindicated owing to the inflammatory condition of the oesophagus, stomach, and intestines. Trional, sulphonal or chloritone would probably prove to be the best remedy for insomnia, etc.

The skin lesions in the cases at Lexington were more benefitted by the application of plain or carbolized vaseline, than any other preparation. Ichthyol, which is so valuable in many skin diseases, has not to my knowledge been mentioned in the local treatment of this disease. The diarrhoea has so far baffled all treatment. A rigid milk diet has been the only palliative remedy. Some of our best men claim that we have no treatment for pellagra. It is the old, old story of skepticism in our profession.

In conclusion will say that without any intention of being an alarmist, that as this disease is spreading so rapidly, and the mortality is becoming so great, that unless our State Boards of Health, backed by Rockefeller's million, succeed in putting a check to it, we may have an epidemic much more severe than that of Italy, that will sweep this country with fearful results.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By J. E. PACE, Scottsville.

The health officer has several problems to deal with, but the greatest problem is the protection of the health of the people. And strange as it may seem, this protection must often be given over the protest of those in the greatest need of it.

Take for example, an epidemic of smallpox. People become offended because we quarantine their relatives and friends who have been exposed but have not developed the disease. They declare the disease is not smallpox because some old person said it was not like folks had forty years ago. And about this time some "Hay Seed" Doctor steps in and says that from what "Aunt Peggy" told him, he is certain it is a case of chicken pox, bold hives or Cuban itch, or some form of eczema. This sets the entire community against the health officer. Dr. Hayseed is petted into the belief that he is quite a deliverer of his people, and if no more cases develop, Dr. H's practice is certain to increase while the health officer receives the scoffs of those who have suffered from vaccination and isolation. But it sometimes happens that about the time Dr. Hayseed is held up as a Moses, some other man or woman is smitten and this time the symptoms are more pronounced. The headache and excruciating backache cause some little fears to arise, the eruption appears and fever subsides and Aunt Peggy who had smallpox years ago, says this is more like she and her brothers had when John died. It is now easier to persuade people to be vaccinated. Dr. Hayseed usually refuses to visit the patient excuses himself on the grounds that the health officer is paid to settle such questions. If the disease is soon controlled, all becomes quiet and very little is said of the trouble. But if other cases develop, the people, as a unit condemn the health officer for not at once controlling the disease.

And what has been said of smallpox is also true of the other contagious diseases. The problem in such epidemics is before us. The difficulties in carrying out our plans must be surmounted even though the way seems hazardous. We must act promptly and without fear of public sentiment. However, we should at the same time, use judgment and never fail to be courteous to those who oppose our plans. And by degrees we educate the people to care more for protection of health and life. But the problem of protection of public health is not solved by stopping with epidemics. We must look for the unsanitary

*Read before the School for Health Officers, Louisville, July 8, 9, 10, 1912.

places in the streets and other public highways and especially in our water supplies. The streets of our towns and villages should be kept drained thoroughly and perfectly clean. The old adage—"Cleanliness is next to Godliness" should be impressed upon every citizen of our Commonwealth. It should be taught from every pulpit and school room in the land, and the mothers and fathers should impress it on every child from the cradle to adult life.

The recent law rendering obsolete the public drinking cup is a great stride in the right direction, and we as health officers should see that the law is observed. The common custom of permitting tuberculous patients to expectorate in public places as court houses, churches and cars should be thoroughly investigated in every county and every possible effort used to prevent the same.

We are glad to note that the physicians throughout the country are educating the people to use proper precaution while nursing tuberculous patients. And shall we hope that in the next fifty years this dreaded disease may be banished from the land?

And yet, typhoid prevails throughout the country. The solution to complete eradication of this disease is perfect sanitary conditions. The water supply often furnishes the germs by multiplied thousands. Proper protection should be given along this line. And yet, we find people become offended if we ask them to empty and clean an old cistern or well. Again, if we enter a house unprotected by screens, we sometimes notice the inmates appear chagrined if we attempt to explain how the common house fly is the carrier of disease producing germs. We all know that this mischievous little pest is the cause of many deaths each year, and we should try to prohibit the breeding by seeing that large heaps of manure and other filth is not permitted to accumulate around livery stables and other public and private places.

Ventilation is another problem that should interest us all. The people should be taught that pure air is one of nature's means of preventing disease. Yet, on entering many of the stores in the towns and cities, we notice the merchant and his assistants looking feeble—not from overwork as they believe, but from poor ventilation. In the homes of many good, prosperous people, we find the windows and doors closed even in hot weather, from the erroneous idea that night air is dangerous.

Public education along these sanitary lines is essential to the well-being of our people. But it is a problem fraught with many difficulties. The public press reaches almost every home, but if we attempt to educate the people in that way, we arouse criticism even from our own profession. It is claimed that

we use the press to advertise ourselves instead of attempting to aid the public.

By asking teachers, ministers and all physicians to cooperate with us in our struggle in the interest of humanity, we may accomplish much. It would be better if the health officer in each county could give his entire time in the interest of sanitation. But the remuneration in most all counties is inadequate to supply such necessary duties.

NEWS ITEMS AND COMMENTS

BOONE—Dr. Richmond, formerly of Tennessee, has located at Verona, this county.

Dr. Perkins, who went to New Mexico a few months ago in quest of health, we are sorry to report, is no better.

Dr. Rodgers, a recent graduate of Louisville, has, we understand, located at Grant.

JEFFERSON—In excellent health and spirits, Dr. Ap Morgan Vance arrived in Louisville several days ago from Frankfort, Michigan, where he has been since August 1st. Dr. Vance's appearance at once put a quietus to the reports of his serious illness of a few days since, which had caused much uneasiness among his friends here.

Dr. Anna Lawrence left last month for Boston, Mass., to remain several weeks.

WEBSTER—Dr. Joseph A. Goodson, of Dixon, who was appointed superintendent of the Eastern Kentucky Hospital for the Insane, on August 8, in Lexington, has arrived to visit his sister, Mrs. Warren L. Reynolds.

CARROLL—Dr. Lillian H. South, State Bacteriologist, gave an illustrated lecture on Hookworm and other diseases before the Teachers' Institute and people at Carrollton, on the evening of August 20th. Dr. South has acquired an enviable reputation as a public speaker and teacher and her lectures are given the closest attention and create a healthy, effective sentiment.

Sodium in Origin of Gout.—Cohn presents arguments and relates experimental and clinical experiences which he thinks justify the conclusion that gout is the result of derangement of the metabolism of sodium and potassium and suggest that abstinence from sodium is an important therapeutic measure. Potassium, on the other hand, counteracts the injurious influence of the sodium and should be given systematically. He has taken the potassium salts himself and given them to patients for weeks and months at a time and never witnessed any injurious by-effects, while they displayed a marked influence in attenuating the gouty process.

COUNTY SOCIETY REPORTS

Barren—The Barren County Medical Society met in Dr. Bott's office, Glasgow, August 13, 1912. Meeting called to order by S. J. Smock, President; T. F. Miller appointed secretary pro tem.

C. C. Howard presented the following case: Male, white, age 40 years, laborer. Three weeks ago began to have colicky pains in bowels, first suppression of urine, later increased flow. Some history of similar attacks six years before. On examination tenderness over right ureter, extending over entire course. No prostatic, nor bladder symptoms. No temperature. X-ray revealed a small stone in each ureter. Gave urotropine, and diuretic. Later infusion of digitalis was given. A mild cystitis developed, with chills and fever. At present urine is normal and patient is doing well. Skiagraphs were exhibited. The interesting point was the almost complete anuria which was explained by the pressure of stones in both ureters, although no pain was felt in the left side.

C. C. Turner presented the following case: Boy 16 years old. Two months ago had sunstroke. Since that time has had oscillations of the eyeballs with twitching of the face, and pain starting in the testicles and radiating through the abdomen. Case discussed and treatment suggested.

Applications for membership were presented from Drs. R. P. E. Starr and C. C. Howard. The same were referred to the Board of Censors.

After arranging for the program for our next regular meeting, the society adjourned to meet next, September 10th, 1912

T. T. MILLER, Secretary pro tem.

Kentucky Valley—The Kentucky Valley Medical Association convened at Torrent, Ky., in its Thirty-second Session on June 25th, 1912.

The morning session was called to order by the President, Dr. W. H. Hobbs, at 10:30 A. M.

I. A. Shirley, of Winchester, gave the welcome address, which was responded to by **Thomas C. Holloway**, of Lexington.

The Secretary read the minutes of the 1911 session which was approved by the society.

W. H. Hobbs, of Rogers, delivered the President's annual address.

Woolfolk Barrow, of Lexington, **J. E. Williams**, of Fineastle, **R. R. Johnson**, of Tallega, and **W. F. Boggess**, of Louisville, were elected members of the Association.

Lillian H. South, State Bacteriologist, of Bowling Green, was elected an honorary member.

The following doctors were in attendance: L. Knox, W. F. Boggess, Thomas C. Holloway, D. H. McKinley, Isaac Brown, Woolfolk Barrow, I. A. Shirley, I. W. Johnson, R. R. Johnson, B. F. VanMeter, J. W. Pryor, W. H. Hobbs, J. E. Lemming, L. H. South, Dunning S. Wilson, John L. Cox, J. H. Evans, J. E. Williams, and Drs. Driver and Congleton.

The first paper of the session was read by **D. H. McKinley**, of Winchester, subject "New Therapy of Syphilis." This paper was discussed by Drs. VanMeter, South, Shirley, Boggess, Pryor, Johnson, Holloway, Knox, Driver, Hobbs and Evans. Discussion was closed by the essayist.

The society adjourned until 1:00 P. M.

The afternoon session convened at 1:00 P. M.

Woolfolk Barrow read a very interesting paper on "Surgical Conditions of the Upper Right Quadrant of the Abdomen." Discussion by Drs. South, VanMeter, Holloway, Hobbs and Evans, closed by Dr. Barrow.

Isaac Brown, of Winchester, read a splendid paper on "Antitoxine in Diphtheria and Membranous Croup." Discussed by Drs. Johnson and South. Closed by the essayist.

J. W. Pryor, of Lexington, read a very excellent paper on "Eugenics," which was discussed by Drs. VanMeter, Boggess and Johnson.

R. R. Johnson, of Tallega, read a paper on "Diarrhea of Infancy and Childhood." Discussed by Drs. Boggess, Hobbs, Johnson, South and Driver, and discussion was closed by the essayist.

W. F. Boggess, of Louisville, read a very instructive paper on "Valvular Heart Diseases."

The society adjourned to meet at 7:30 P. M.

The night session was opened by J. W. Pryor acting as chairman.

I. A. Shirley, of Winchester, lecturer for the Rockefeller Institute, gave a splendid illustrated lecture on "Hookworm Diseases."

Lillian H. South, State Bacteriologist, gave a very instructive and entertaining illustrated lecture on the bacteriology relative to preventable diseases.

Hon. James Mott McDaniel, of Beattyville, made an eloquent and entertaining speech on the "Hookworm as Seen by the Layman."

The session was closed by an illustrated lecture by **Dunning S. Wilson**, of Louisville, who is Director of the Jefferson County Sanitarium for the treatment of tuberculosis.

The following officers were elected for the ensuing year: I. W. Johnson, Stanton, President; L. Knox, Bowen, Vice President; J. H. Evans, Beattyville, Secretary.

The society adjourned to meet at Torrent, 1913, the exact date to be fixed by the officers.

J. H. EVANS, Secretary.

W. H. HOBBS, President.

Muldraugh Hill—Meeting called to order at 10:30 A. M., August 9th, 1912, in the City Hall, by Vice President Willmoth; about thirty members being present.

D. O. Hancock, of Henderson, honored the society with his presence.

Dues being paid and the reading of the minutes passed, **C. Z. Aud** made a motion that the Secretary write to the doctors of Grayson coun-

ty to induce them to take a more active interest in the society. Carried.

The election of a President was next in order; D. C. Donan's name was presented to the society and he was unanimously elected to that office.

After the President had assumed his duties Dr. Hancock was conducted to the rostrum as a guest of honor. He thanked the members for their courtesy in a few happy remarks.

SCIENTIFIC PROGRAM.

A. D. Willmoth reported a case of stricture of the oesophagus caused by ulceration following typhoid fever. The patient was entirely relieved by gastrostomy with retrograde dilatation at first, later by dilatation per os. The speaker emphasized the importance of watching our typhoid cases and those showing difficulty in swallowing during convalescence should be taken in hand before the stricture has had time to contract to such a degree as in this case.

J. H. Ridgway read a paper on "Kidney Infection," with report of cases.

Wm. H. Wathen spoke to the point of "Tuberculosis of the Kidney and Bladder," showed the ease of making a diagnosis; said that cases were always descending infections, usually unilateral at first, and due to hemogenous infection; a painstaking examination should be made and sufficiency of other kidney tested. In cases where diagnosis is positive, nephrectomy should be done at an early date, but bladder irritation tends to persist.

B. F. Zimmerman spoke of the frequency of infections of the kidney, usually due to colon bacillus. Keep up active elimination; urinary antiseptics. One should not make the mistake of treating the bladder when kidney is at fault. Make a cystoscopic examination and catheterize the ureters. Don't, however, use catheter in ureter in old bladder infections, as you might start an ascending infection of the kidney. Irrigate pelvis of kidney with ureteral catheter, and follow by injection of nitrate of silver or argyrol. Obtain urinary specimens in women by catheter.

Curran Pope spoke of infection of the kidney in cases of myelitis. Had no faith in stock vaccines. Thought there were many strains of colon bacilli. One should use autozenous vaccines, usually mixed, controlling cases by repeated examinations. Use mixed vaccine of all organisms present. High frequency current will produce an active hyperemia that will assist Nature in ridding the system of infection. One must beware of giving vaccines too frequently. Has cleared up cases even in ataxies.

Bernard Asman spoke of colon infection of the bladder and the source of supply. Due to lesions in anal wall that travel to bladder by means of lymphatics and blood. Therefore, a rectal examination should be made in these infections.

W. C. Dugan spoke of Dr. Willmoth's case;

thought these cases were very rare. These cases are very difficult; hard to reach oesophagus through stomach; typhoid strictures don't open up as a rule. Reported cases. Speaking of Dr. Ridgway's case, took exception to Dr. Wathen, in that tubercle bacilli were not found unless fluid was injected into guinea pigs.

E. W. Montgomery reported an interesting case of infection of bones of the leg. Reported to know if case would entirely recover or have some shortening.

D. O. Hancock reported a case of pregnancy complicated with ascites, with repeated tapplings, drawing off large quantities of fluid. Labor followed last tapping. Mother delivered with forceps of living child.

A. D. Willmoth and **W. C. Dugan** in discussion of Dr. Montgomery's case agreed that no shortening would occur. Dr. Dugan said there was no danger of shortening on removal of shaft of bone, as growth occurs from the epiphysis.

The society adjourned for dinner at 12:00 M., and reassembled at 1:00 P. M.

Curran Pope delivered an address on "Psychoanalysis as a Method of Treatment," in his usual incomparable manner.

On motion of **A. D. Willmoth**, discussion of all papers was deferred to the end, in order that the members who had to leave early might hear as many of the papers as possible.

H. D. Rodman being absent, his paper was passed.

D. O. Hancock, of Henderson, then addressed the society on the progress the State Society was making, its connection with the State Board of Health, its position in regard to legislative enactment of laws for the benefit of the health of the people, the prevention of disease and the eradication of undesirable charlatans and quacks. He spoke also of the necessity for an uniform program for State and County Societies.

D. O. Hancock's remarks were enthusiastically received, and the members felt honored that he should have been there to address them.

G. G. Thornton read a paper on "Stomach Troubles," and their management by the general practitioner.

W. H. Wathen, in discussing Dr. Thornton's paper, said that medical text-books require to be entirely lost sight of and the subject discussed from a rational standpoint. Spoke of the disease of the blood-vessels, kidneys and abdominal organs causing stomach trouble, and related illustrative cases; gall-stones, appendicitis, pelvic disorders, ulcers (duodenal). Shows the surgical aspect of these conditions.

Curran Pope, referring to Dr. Hancock's address, spoke of the necessity of the State officers regulating the dates of meetings of the district societies, to get dates that do not conflict.

Regarding Dr. Thornton's paper, disagreed with Dr. Wathen as to the surgical aspect of these cases. Digestion is not only a question of

secretion, but also a question of dynamics. Thought much relief is to be had from mechanical appliances in cases of splanchnoptosis. Relief due to improved circulation and better position. Use a tube instead of emesis to clean out the stomach. He objected to the indiscriminate use of the ternas hysteria and neurasthenia, and suggested the words hysteroid and neurosthenoid in their stead. He advocated the bismuth meal and X-ray in mopping out the stomach in cases of ptosis.

G. C. Hall spoke of the incidence of refractive errors in cases with digestive disabilities, especially those doing much near work and getting very little exercise. He cited several cases and referred the members to a perusal of Gould's Biographic Clinics.

Bernard Asman called the attention of the society to the occurrence of hemorrhoids in cases of digestive disturbances, and cited cases where relief had followed the surgical correction of this condition.

J. L. Atkinson referred to the diverse causes for these conditions and the difficulties in their proper way to eat and regulate their diet. He thought the surgical aspect of these cases was a late development, due to neglect or improper attention in the early stages.

D. O. Hancock told of the experience of the Henderson County Society and the benefit to the members from papers dealing with this subject in the form of a symposium.

G. G. Thornton, in closing, thanked the members for their discussion, and related a number of such cases. He did not think the stomach tube applicable in all cases.

Bernard Asman read a paper on ano-rectal abscess in its relation to fistula. At the conclusion of the paper he exhibited drawings showing diagrammatically the different varieties of abscess.

W. T. Nichols asked to be excused from reading his paper, as he had not had sufficient time to prepare it. He was excused under promise to read the paper at the December meeting.

B. F. Zimmerman delivered an address on the Treatment of Uterine Displacements.

This concluded the program and the various papers were now open for discussion.

W. H. Wathen opened the discussion. Said that simple cases of version or flexion, without adnexal disease, require no treatment. Pessaries should no longer be used, but they were at one time a necessary evil. He discussed the evolution of the present day conception and handling of these cases. Thought it better to open the abdomen in order to see all the pathology. Kelly's suspension operation is a suitable operation where the child bearing period is passed or of no moment. Finally discussed cases where pelvic floor is diseased. Cystocele is the hardest of all to cure. Described his technique in such cases. Thought some cases past child-bearing period best relieved by taking out uterus per vagina.

J. L. Atkinson doubted if displacements were ever without symptoms. In some cases these are bearable and the woman suffers rather than submit to a surgical operation. Thought the pessary still had a place in the treatment of these cases uncomplicated by large uterus, or disease of the pelvic floor. The field is narrow, but they can be used if proper instructions are given patients. Thought surgical treatment often disappointing.

A. D. Willmoth discussed the varieties of these conditions. One must consider that these cases are not surgical emergencies but elective operations, and one is severely criticised for a death or failure. Thought pessaries still had a place but they must fit. Considered the fact, also, that operations sometimes fail. One should try to see the case from the viewpoint of the patient. He discussed the various round ligament operations, and thought in old women it was best to do an hysterectomy.

G. G. Thornton said he had had absolute failure from the use of pessaries, and had long since discarded them.

Following this, a general informal discussion of the various papers ensued, which kept up till nearly train time, when the meeting adjourned to meet again in December.

The close of this meeting finds the society in a prosperous condition, with a steadily growing membership and a constantly increasing interest in the meetings.

One of the finest features of the sessions is the heartiness and good will with which every one enters into the discussion, and the entire absence of any friction or personal feeling.

We bespeak for our new President a continuation of the good will and prosperity that now reigns in the society, and know he will endeavor in every way to still further advance its interests.

GALYORD C. HALL, Secretary.

Duodenal Ulcer.—Dietrich states that evidences of gastric ulcer and of hemorrhagic erosions were found each in 1.1 per cent. and of duodenal ulcer in 0.4 per cent. of 8,538 necropsies at the Hamburg hospital, 1908-1911. In twenty-four cases the duodenal ulcer was single and in ten multiple; in four there was an associated gastric ulcer and in two hemorrhagic erosions in the stomach. In none of the cases was there a history of an extensive burn, but in no less than eight of twenty-six cases the duodenal ulcer followed an operation in which the omentum or mesentery had been ligated. A thrombus had evidently formed and worked its way backward against the current, and injured the duodenal lining where it finally lodged. He summarizes these eight cases, emphasizing the rapid progress of the ulceration in these conditions and the usual early erosion of an artery that follows.

PITUITARY GLAND.

(A PHARMACOLOGICAL CONSIDERATION)

By VIRGIL E. SIMPSON, Louisville.

EFFECTS ON THE CIRCULATORY SYSTEM.

Introductory.—In 1895 Oliver and Schafer¹ found that the pituitary gland caused a rise in blood pressure. The entire gland was used in their experiments. In their published report they concluded that it was not as efficient as suprarenal gland with which they had been working during the previous year. Howell² demonstrated that only the infundibular portion of the gland possessed this pressor property. This was confirmed the following year by Schafer and Vincent³ and since accepted by all investigators. Halliburton, Candler and Sikes⁴ established by their work in 1909 that the effects that had been obtained in the use of the glands of lower animals held good in the human gland also.

Local Action.—No appreciable effect is obtained when applied to the unbroken skin. When used on denuded skin surface or on mucous membrane the vessels are promptly contracted resulting in an ischemic condition. The sensation of the field thus treated becomes obtunded to a degree, not on account of any influence on the sensory nerve endings *per se*, but merely as a direct result of deprivation of normal blood supply. Injected subcutaneously, the vessels with which it comes immediately in contact are powerfully contracted rendering the area almost bloodless. The possibility of necrosis and death of tis-

sue, when used in concentrated strength and large quantities in this manner, must be borne in mind though this likelihood is less than in the use of supra renal gland. In fact, it may be stated here that the effects of pituitary throughout the circulatory system are less spectacular though more prolonged than suprarenal.

Internally.—The heart is made to contract less frequently and the force of its contractions augmented. The systole is more complete and in the exposed heart there is no difficulty in noting the paler color of the muscle; the organ also becomes smaller, a result that can be accurately determined by the oncometer. There has been some dispute as to the cause of this slowing of the heart action. Liven⁵ and Garnier and Thonon⁶ claiming it due to stimulation of the cardiac-inhibitory center, while Howell and de Cyon argue that it exerts a direct influence on the cardiac muscle. Wiggers⁷ rides with the hounds and runs with the hare in claiming that when the heart is slowed synchronously with the increased pressure it is due to stimulation of the vagus center and that when it appears late it is due to direct action. Both camps of disputants have missed the chief factor viz: *the tremendously increased peripheral resistance*. It is a fundamental law that an increase of pressure produces a corresponding infrequency of cardiac contractions when kept within reasonable limitations. It requires more power to drive the blood through blood vessels that are contracted and if the heart is normal it rises to the emergency, contracting more forcibly but less frequently, the slowing bearing an inverse ratio to the increased power. If the slowing were due to central action then vago-

tomy would absolutely prevent it. Likewise, the use of atropine prior to the use of pituitary would anticipate the infrequency of contractions. But, both experimentally and clinically, pituitary slows the heart after the administration of atropine and section of the vagi. It will also be noted that the slowing is concomitant with the rise in pressure. While the question of the presence of more than one active principle in pituitary affecting the heart, one pressor the other depressor, has been much mooted nothing convincing has been adduced and the constrictor influence remains the greatest factor, at least, in the production of a slow heart.

The *Blood Vessels* are promptly and powerfully contracted. The caliber of vessels may be lessened by direct influence of a drug on the vaso motor nerves or, by affecting the muscles of the vessel walls, and finally by its influence on the vaso motor centers. Which of these three is involved in the case of pituitary action? The blood vessels will contract after the destruction of the brain and cord. Pith a frog, inject pituitary extract and on perfusion it will be found that the flow of fluid through its vessels is much less than before pituitary was injected. If a section of a vessel be removed cutting off all its nerve supply it will still contract when perfused with a solution of pituitary extract. That the contraction caused by pituitary is due to its influence on the musculature is, then, a demonstrable fact. The greatest effect is observed on the smaller vessels as these possess a relatively greater thickness and hence a relatively greater power of contraction than the great arteries of the body. Another interesting question is, does pituitary act on all vessels alike? This can be determined by placing segments of vessels in Ringer's solution connected according to the method of Meyer. The drug is then added to the solution. The femoral, carotid, mesenteric and coronary all contract. With the renal artery, however, there is a relaxation—that is, there is a dilatation in the intact renal vessels; when the vessels are intact the kidney increases in size and the venous outflow from the organ is much increased. The coronary and the renal arteries are affected directly opposite from the result secured when supra renal gland is used, since the latter dilates the coronary and contracts the renal vessels. We have not been able to determine whether the cerebral vessels are affected one way or the other and a careful survey of the literature brings no information to the surface on this point. The same is true of the pulmonary vessels. The arteries distributed to the uterine are contracted independent of the striking action on the uterine muscle to be noted later.

The *Blood pressure curve* is a characteristic

one. There is a slight fall observed immediately after injection, followed in from thirty to sixty seconds by a decided rise. The rise is not so rapid as in the case of suprarenal gland but the maintenance of that rise is much more prolonged. The effects persist, generally, from one to two hours. Bell⁸ reports a case under the care of his colleague, Jeans, where the pressure was sustained for twelve hours. He believes that a better effect on pressure is noted when the animal is in shock than if in a normal condition. In his operative work he claims to have verified this on his patients repeatedly and while he does not minimize the good offices of normal saline, he thinks that its function is to maintain the improvement produced primarily by pituitary. In shock there is usually a vasomotor paralysis and normal saline can not possibly relieve this.

Effects of Repeated Dosage.—Attention has already been called to the initial fall of pressure after the first injection. Each subsequent injection produces less and less effect until the preliminary apparent depressor effect may be the only response. This does not seem to be the result of paralysis of the muscle fibre but to be a progressive loss of responsiveness to the agent. Schafer and Vincent⁹ concluded from their experiments that the infundibular portion of the gland contained two constituents—one raising the blood pressure and the other lowering it. The pressor principle being insoluble in alcohol and ether while the depressor principle is soluble in either. They argue that the action of the pressor principle is prolonged while that of the depressor is evanescent. Bell and Hick showed that pituitary increased the calcium content of the blood. There are some reports in the literature that tend to show that pituitary extract, like suprarenal, causes atheromatous changes when long continued. These are, as yet, too meager to base any positive statements thereon and we have not had the opportunity to make any personal observations in our laboratory experiments.

THE GENITO-URINARY SYSTEM.

Effects on Kidney Function.—Schafer and Magnus¹⁰ in 1901 found a hormone in pituitary extract which affects the kidney function by increasing the urinary output. This was an addition to our knowledge which should, probably, have been anticipated. They learned that there was a renal congestion following intravenous injection of the extract and finding a close relationship between this congestion and the general rise in blood pressure, a conclusion that the diuresis was due to circulatory changes was not unwarranted. The increase in urine is a fairly constant one and the increase in size of the kidney is rather

prompt. Three explanations could be offered for this action: (a) That the extract dilates the renal vessels by selective action. (b) That the general rise in blood pressure passively overcomes whatever constrictor action there may be on the renal vessels. (c) That there is a direct influence on the cellular structure. Schafer and Herring¹¹ attributed the diuresis to cellular stimulation because they observed that the increased flow of urine outlived the rise in pressure of the general circulation. Pal¹², who did most of his work with cats, found that even after curare the bladder would fairly rapidly be filled following injections of pituitary and he concluded that it dilates the peripheral vessels of the pelvis but contracts those of the proximal section. In search of an explanation, Sollman found that when the spleen was left in contact with the central nervous system and perfused with pituitary extract an intravenous injection of the extract caused some dilatation of the splenic vessels, seemingly establishing a central dilator action. Reasoning by analogy, he leans to the opinion that the diuresis is produced in somewhat the same way. Ott and Scott¹³ believe that the diuresis is due to direct cellular action and that the renal vessels are uniformly dilated. They are inclined to think that the general rise in pressure plays a small part in the diuresis. Houghton and Merrill¹⁴ using the technic proposed by Sollman conclude (1) that the increase in urine in anesthetized animals depends chiefly upon increased blood pressure rather than specific action on the secretory cells; (2) that while it is possible that some specific action does occur, it is less than in the case of a 1 per cent saline solution, and (3) that pituitary brought directly in contact with these cells causes less effect than sodium chloride. While for the present the explanation of the diuresis may seem largely academic these facts are of practical importance: (a) There is a unanimity of results in experiments as to the occurrence of diuresis. (b) Perfusion of the kidney with the extract will invariably cause a constriction of the renal vessels. (c) Repetitions of doses cause less effect on general blood pressure while the increase of urine is maintained. (d) The pituitary is found to be frequently enlarged, post mortem, where polyuria was a symptom. (5) It will often re-establish the flow after suppression following operative procedure or general anesthetics.

Action on the Uterus.—To Dale¹⁵ probably belongs the credit of first demonstrating the influence of pituitary on the uterine body. He incidentally mentioned his experiments with this gland in a paper on ergot. Bell¹⁶ claims to be the first to have used it clinically. The effects are prompt, are probably as pronounced as from ergot and a more pro-

longed contraction is not only observed but retraction is good. In those cases where the uterus was exposed to the eye of the observer during Caesarean section the organ was observed to contract into what is described as a "blanched ball," and subsequent relaxation is of but moderate degree. Subinvolution of the uterus, due to defective contraction and retraction, is one of the dangers of Caesarean section, especially when performed before the onset of labor and the routine use of pituitary extract at the termination of the operative procedure and for a varying period thereafter would seem a warranted proposition. There is no doubt that post partum hemorrhage can be as effectually stopped by means of pituitary as with any other drug. The action is quite prompt when injected into the uterine structure. The character of the contractions resemble those of the normal uterus. It seems to act best after spontaneous contractions have begun and stopped. Bell believes, as a result of his experiments together with his clinical work, that it acts better on the atonic organ than on the normally contracting one—a claim which he makes with reference to the blood vessels also. Since it causes prompt contraction of the uterus the same precautions with reference to administration before completion of normal labor should be observed as is recognized with other agents of this class. Ott and Scott¹⁷ state that the contractions of the human uterus caused by pituitary are more prolonged than those induced by any other drug. The action is chiefly peripheral as shown by placing an isolated and active uterus in Ringer's solution and noting the powerful contractions after injection of the extract. White¹⁸ reports a case of instrumental delivery at term under spinal anesthesia, the woman having pneumonia, in which there was post partum hemorrhage, due largely he believes to the tropococaine used in inducing the anesthesia; the extract was used in the buttocks and prompt contraction was secured. Fischer¹⁹ reports his experience in a series of fifty obstetric cases. In thirty pituitary was used to augment the contraction before labor was completed. He noted effects in from one to twenty minutes—the average being six minutes—while the action lasted from two to four hours after which time the pains became less frequent and he thought, weaker. The effect seemed more pronounced the more advanced the labor. These were cases where he thought forceps would have to be used; some of them having feeble, wasted muscles and atrophied uterine tissue. In those cases where the extract was used alike to accelerate labor in the interest of mother or child and in those having post partum hemorrhage, the results were satisfactory. In our own experience, the extract has been used in

three cases of frank post partum hemorrhage; the contractions were satisfactory in all of them, while in one absolutely nothing else was done to check it save an injection directly into the uterine muscle, it has been used by way of precaution in normal cases for nearly two years with more frequency than ergot; its use in small doses to augment feeble contractions before delivery has likewise served us well.

PITUITARY AND METABOLISM.

Effects of Removal.—The dictum of Horsley that no effects followed removal of the pituitary gland, coming from such high authority, no doubt kept this organ on the neglected list for a long time. But Paulesco²⁰, by an improved technic of approach to the base of the brain and removing the gland in its entirety, found that a uniform and peculiar train of symptoms invariably followed by death in two or three days occurred. He later concluded that separation of the stalk caused the same results as removal. Cushing and Redford²¹ found Paulesco to be partially right; that mere separation of the stalk does not cause death necessarily; that loss of the posterior lobe leads to no obvious disturbance in the animal's condition; the symptoms of such removal as stiffness, unsteadiness of gait, lowering of temperature, slow pulse and respiration, irregular muscular contractions and tetany-like tremors, lethargy with coma and death ensuing. In every animal that survived some viable fragments of the anterior lobe were found remaining. The great Horsley had erred, not so much in his conclusions but in his technic. He thought that he had removed the gland in its entirety but failed. Partial removal of the anterior lobe leads, in young animals, to a persistence of infantilism—undersize, no secondary sexual characteristics, hypotrichosis and a subnormal temperature; older animals under the same conditions show a tendency to return to the infantile type, with loss of spermatozoa, atrophy of testicles, absence of mitosis, etc., with histological alterations in the islands of Langerhans, the thyroid and a glycosuria.

Effects of Dissected Conditions of the Gland.—Pierre Marie, in his classical paper on Acromegaly in 1886, was the first observer to call attention to the pituitary gland to account for errors of development or manifestations of disease. While some of his conclusions have been since challenged yet he placed the pituitary on the pathological map. It is, perhaps, not true that tumors of the gland always result in acromegaly for Frolich and others have described a creditable number of cases of tumors of this organ with no acromegaly, but adiposity and infantilism instead. But since overactivity of the anterior lobe is now recognized as the most active functional fac-

tor in the production of acromegaly and since an exaggeration of function is not necessarily accompanied with any appreciable increase in size, the real import of Marie's work is not lessened. Acromegaly is the result of hyperpituitarism after the organism has become fully matured. When it occurs in the young a condition known as gigantism, which is closely related to acromegaly, ensues. This statement was first made by Meigs and the consensus of opinion still supports it. Evidently a close and interesting relationship exists between adiposity and hypopituitarism. Friedenreich²² believes that obesity is not infrequently due to disease of the hypophysis or an impairment of its function in consequence or as a complication of disease elsewhere. Persistence of infantilism or a reversion to that type when occurring in adults and insufficient activity of the gland have already been referred to under the heading "effects of removal."

Effects of Administration.—The experiments of Thompson and Johnson²³ showed that ingestion of the entire gland led to a loss of weight. They accounted for this by a stimulated metabolism due to the posterior lobe. Sandri²⁴ observed no effects on mice from two months' feeding of the anterior lobe and a noticeable loss with arrest of development when the posterior lobe was given. Schafer²⁵, however, has demonstrated that rats fed on anterior lobe showed a definite increase over controls. Goetsch, working in the Hunterian laboratory, obtained results supporting Schafer. Cushing²⁶ states that the most striking sequence of anterior lobe ingestion is a temporary pyrexia of from two to four degrees (Centigrade). Dunan²⁷ has made an extensive study of the influence of pituitary on metabolism. He has found that the toxicity of the urine is increased, nitrogen elimination diminished and that glycosuria is constantly present. This latter statement introduces the interesting relationship between carbohydrate tolerance and the pituitary gland. Goetsch, Cushing and Jacobson²⁸ have published the results of a series of experiments which tend to throw some light on this relationship. They found that in partially hypophysectomized animals a transient glycosuria usually showed immediately after the operation but this condition soon yielded to a markedly increased carbohydrate tolerance. This tolerance could be reduced to or below the normal very readily by administering extracts of the posterior lobe. In other words, excessive activity of the gland or over-dosage results in glycosuria, while lessened secretion, either from removal or disease, results in a greatly increased carbohydrate tolerance. A satisfactory explanation of the varying clinical picture of acromegaly is thus afforded;

hyperfunction obtains early in the disease—hyperfunction not only of the anterior lobe which leads to the skeletal changes, but of the posterior lobe as well which ends in glycosuria; in the latter stages there is hypofunctioning of the posterior lobe which results in increased tolerance and disappearance of sugar. Of, perhaps, equal interest is that group of cases presenting interpenduncular tumors, tumors of the posterior lobe, etc., which cause an obstructive hydrocephalus damming back the posterior lobe secretion. It is possible that the transient glycosurias frequent in basal fractures are due to temporary irritation of the hypophysis. A number of cases have been reported which were diagnosed as diabetes mellitus and insipidus where post mortem showed them to be due to diseased conditions of the posterior lobe. These are not such rare conditions and many clinicians believe that disease of the pituitary are as frequent as those involving the thyroid.

PITUITARY AND THE GONADS.

Hypogonadism.—Fiehera²⁹ conducted a series of experiments on 65 animals, including rabbits, guinea pigs, cattle and buffalo, to determine the effects of castration on the pituitary. He found that the removal is followed by hypertrophy of the anterior lobe with hyperplasia of the eosinophilic cells. His conclusions have been confirmed by Schutz³⁰, Tandler and Gross³¹ and Soli and Kon³², the latter observing eight cases in the genus homo. The effects of this operation seem confined to the anterior lobe and suggest that the pituitary may normally be held in check by the secretions of the gonads and when removed it manifests increased activity leading to altered metabolism and overgrowths. Church³³ called attention to the fact that disturbances of the pituitary are frequency associated with sexual anomalies. Cessation of menses in the female and impotence in the male are recognized initial symptoms of acromegaly and the same is true of pressure from neoplasms on the pituitary. The restoration of menses after removal of pituitary tumors conclusively proves this relationship. Cushing³⁴, Monier-Vinard³⁵ and others have reported atrophy or aphasia of gonads in both sexes associated with tumors of the pituitary.

Hypergonadism.—No evidence has been found of any effect on the pituitary by increased activity in the male. In the female, pregnancy causes an increase according to cytological studies made by Launois and Mulon³⁶ and others. In a careful comparison of weights and cytological condition of the gland from 85 pregnant women Erdheim and Stumme³⁷ found both pituitary hypertrophy and cellular activity accompanying pregnancy. That these changed conditions may

be due to altered metabolic accompaniments of pregnancy has been suggested by Hoskins³⁸.

INFLUENCE ON THE GASTRO-INTESTINAL TRACT.

Motility.—Peristalsis of both the stomach and intestine is increased. On pithed rabbits the movements are rather violently performed, and local blood pressure raised. The effect is noted in from five to twenty minutes when the extract is given intramuscularly. This action seems to be the result of its influence on the muscular tissue rather than on the myoneural junction. Bell³⁹, who has done much pioneer work with pituitary, speaks rather enthusiastically of its use in paresis of the bowel and considers it more efficacious than eserine. In his surgical work he had an opportunity to test its reliability in post operative acute gastric dilatation. In the same year Bell and Hiek⁴⁰ experimented with it on paralytic distention of the bowel with satisfactory results. Bidwell⁴¹ made a series of observations on unselected cases after abdominal operations to note the effects on peristalsis. He concluded that a satisfactory influence in overcoming temporary paralysis due to exposure was exhibited; there was earlier passage of flatus, absence of abdominal discomfort and a smaller amount of purgative was needed. He used three injections of 1 c.c. each during the first twenty-four hours, giving the first six hours after the operation and the other at six hour intervals. Prompt and satisfactory results have been reported in cases of ileus by several observers; in these cases a repetition of dosage in from thirty to sixty minutes was used. We have had some experience with the extract in acute gastric dilation, and while it may be difficult to dissociate the effects of lavage from those of pituitary, yet the results have seemed to be better when it was used than when lavage alone was employed. Only in a large series of cases could satisfactory comparisons be drawn as to the number of washings and the length of time after the appearance of the condition that they had to be continued, but it seems to us pretty certain that pituitary produces a sufficiently prolonged effect on the muscle fibres to materially shorten the life of the condition. We wish to state, emphatically, that there is no single measure comparable to the timely use of the stomach pump. However, there occur too frequently cases when it seems that the musculature of the stomach has lost absolutely its power of contraction and will refill again and again after lavage until death occurs. It would also seem not unreasonable to accredit pituitary with a prophylactic mission and its use immediately after operation in such cases as have necessitated the long exposure and trauma incident to certain proced-

nres may, not infrequently, forestall the advent of a condition that causes dismay to even a veteran operator.

Gland Activity.—In 1908 Pemberton and Sweet¹² announced their conclusions that pituitary extract inhibited the flow of pancreatic juice. In their summary of their experiments they stated that they believed that this action was the result of an influence on the cells of the organ rather than the product of circulatory changes. Edmunds¹³, the following year, took issue with this conclusion arguing that the inhibitory action was entirely the result of changes in the blood supply. Pemberton and Sweet continued their experiments and in 1910 reaffirmed their original conclusions as to the mode of action, thus: (a) that pituitary inhibits the pancreatic activity. (b) that this inhibition occurs independent of the blood supply. (c) That it occurs also when the pancreas is stimulated by its normal excitant in the duodenum—hydrochloric acid.

DISCUSSION.

F. C. Askenstedt: I came here expecting to hear a paper that was well worth hearing, and I am only disappointed in that it was not longer, because I enjoyed every word of it.

The pituitary gland has recently been extensively studied, much to the advantage of the clinician, and some very practical points have been observed. Not long ago it was thought that the pituitary body was a rudimentary gland,

like the pineal gland, because its anterior lobe is simply a diverticulum of the fauces of the foetus, and if we examine it histologically, we find that it is almost identical in composition with the thyroid. Its posterior lobe, on the contrary, is a nerve center, and contains as many as ten different kinds of cells, showing the high degree to which it has been differentiated.

While the doctor was reading his paper it occurred to me that Sajous' views seem to harmonize with many of the points he brought out. Sajous, after thorough investigation, has promulgated the theory that the posterior portion of the pituitary gland is a nerve center concerned chiefly with the thyroid and adrenal glands; for, while it has other functions, this is the main one. Furthermore, that it has no secretion of its own, and that stimulation or irritation of this gland causes excessive function of the thyroid, which, in a young and growing child, leads to unequal growth, or acromegaly. Stimulation of the pituitary also causes increased function of the adrenal gland, the main functions of which are oxidation, and contraction of the blood vessels. This theory would seem to explain the fact that contraction of the blood vessels occurs when the pituitary gland is stimulated. We find that the pituitary extract itself has a contractile effect upon the blood vessels, which is probably not caused by direct stimulation of the suprarenal gland, but because the posterior lobe of the pituitary is largely composed of the same type of cells as are the adrenal gland—chromaffin cells—and it is this substance that causes contraction of the arteries. That the pituitary gland has no secretion of its own seems to be supported by the fact that, in hyperthyroidism, the symptoms can often be relieved by injecting the extract of the pituitary gland, causing contraction of the blood vessels that are dilated by the hyperthyroidism and thus alleviating the symptoms. In this respect pituitary extract might be compared to adrenal extract, but the former can be taken by the mouth to greater advantage than can the suprarenal. We know that adrenal extract is very slowly absorbed by the mucous membranes. Furthermore, as we have heard to-night, pituitary extract stimulates the secretory function of the kidneys, while adrenal extract contracts the blood vessels of the kidneys, consequently causing them to excrete a decreased quantity of urine.

One point that we might well bear in mind is the fact that the repeated administration of pituitary extract will soon lose all effect. That is, a second dose given shortly after the first one is almost devoid of result, and a third dose given immediately afterwards will not contract the blood vessels at all, but may even dilate them, as stated by Dr. Simpson in his paper. On the contrary, if we want a sustained effect, by using adrenal extract, we can continue the contracting effect by each dose. As the essayist stated, the

effect of pituitary extract, while a little slower in manifesting itself, is more prolonged, as a rule, than that of adrenal extract, but if we desire to continue the effect, it can be done to better advantage by using the suprarenal extract. Not in every case, however, do we find that the pituitary extract produces a more prolonged effect than that of adrenalin. Only a short time ago, I tried pituitary extract, 1-100, in a patient in the last stage of tuberculosis, and obtained an increase in the tension of 5 mm., lasting about twenty minutes. Two days later (on the day he died) I administered adrenalin, 1-1000, and obtained a rise in the pressure of from 10 to 15 mm., lasting for fully half an hour.

The use of pituitary extract and adrenalin seems to be mainly indicated in cases of shock, or in cases of threatened death under an anesthetic. In such cases we want a remedy that acts promptly and surely, and I know of none, except nitroglycerine (which has an opposite effect so far as the blood pressure is concerned), that will act as promptly as adrenalin. In patients who are extremely exhausted from disease we do not get much response from drugs, because the reactive force is exhausted, but if pituitary or adrenal extract is used we supply the very stimulus that we have been endeavoring to elicit by means of drugs and of course it acts much more promptly.

I wish to sound a note of warning in connection with the use of these extracts, however. Never use them in cases where there is already high tension, because there is danger of rupturing the blood vessels. I know of one instance in which the tension was increased as much as 55 mm., under the administration of adrenal extract, and you can easily imagine what the effect upon an already high tension might be, possibly leading to hemorrhage in the brain or in the suprarenal gland. We should also be cautious in administering them to children, as they seem especially prone to adrenal hemorrhage. Loeper and Oppenheim found adrenal apoplexy in 45 per cent of their autopsies of infants.

Wm. A. Jenkins: Pharmaceutical considerations of any therapeutic agent are, in a sense, dry, but this fact may be advanced in extenuation, they are necessary. However, I am sure that if any real advance is to be made along this line in the future, it will be the outcome of a double consideration—pharmacological on the one hand and clinical experience on the other. The real value of any therapeutic agent can only be determined by due consideration of the two sides of the question.

I suppose that Cushing has experimented with, operated upon, and understands this gland more thoroughly than any other man in America—or any other country for that matter, and in his recent book on "The Pituitary Body and Its Disorders," you will find all that is obtainable on the subject.

The last speaker is mistaken in the statement that there is an absence of secretion in the posterior portion of the pituitary gland; most authorities are inclined to believe that there is a secretory function.

In regard to the administration, internally or subcutaneously, of extracts of this gland, or of suprarenal gland (which are very closely analogous), it has always been my opinion that very little in the way of results can be obtained from the administration of adrenalin by the mouth, and this opinion is corroborated in an article on the subject which appeared in the last issue of the *Journal of the A. M. A.* It is certainly true that pituitrin, used subcutaneously, has about the same range of action as adrenalin, and it is equally true that, while the effect of the former is not so spectacular, it is more prolonged.

I think the explanation of the fact that it does not have any particular effect upon the blood vessels of the brain is this: From the standpoint of anatomy, we know that there is no especial vasomotor mechanism for the blood vessels of the brain, therefore, the blood pressure can only be raised in the brain by acting through the systemic circulation and thus raises the blood pressure generally.

I have had a limited experience with pituitrin and have used it in the same conditions as I would suprarenal extract or adrenalin. I had a very happy experience with it in three labor cases which were of the atonic type referred to by the essayist. In these cases, where there seems to be nothing wrong except that the uterus has simply lost its tone and quit working, there is no question but that the administration of pituitrin is of considerable value. The only times I have used it was in the second stage, when labor was well along, and I am convinced that it was beneficial.

My experience differs from that of Dr. Askenstedt in that a second dose produced about the same influence as the first. However, I have never given a second dose immediately upon the heels of the first, usually waiting two hours or even longer, and I am positive that in one case it produced very good results. In reading the literature on the subject I noticed that pituitrin is being used very extensively in the class of cases referred to, and in some instances three doses have been given at intervals of two hours between doses.

E. S. Allen: I think Dr. Simpson is to be congratulated upon the masterly manner in which he has gone over the literature on this very interesting subject, as well as giving us the benefit of his personal experience with pituitary extract. In the management of post-operative conditions which we so much dread, it would seem that, if we have here an agent that will contract the stomach, bring to life a practically dead peristalsis, stimulate the heart and blood vessels,

make the kidneys excrete and the bowels move, we ought to feel thoroughly satisfied.

I do not think there is any doubt that this is a great therapeutic agent in certain conditions, especially shock. It is greatly preferable to adrenalin because the effect of the latter is so evanescent. Furthermore, we have, in pituitary extract, an agent which seems to act directly upon the musculature of the blood vessels. We have a great many so-called stimulants which act through the vaso-motor system, exhausting its energy. We know that in patients with vaso-motor paralysis caused by shock following operations, the vaso-motor centers are, to a certain extent, anemic; the heart is weakened and more or less relaxed, and it has not enough energy to pump the arterial blood into the medulla in sufficient quantities to furnish proper nutrition to the vasomotor centers. In such cases by giving an hypodermic of strychnia, we exhaust whatever reserve energy may exist, and the patient finally dies as the result of paralysis of these centers. Practically the same thing occurs when we introduce saline into the vessels; it increases the pressure enough to force a sufficient amount of blood into the medulla, but the reserve energy is soon exhausted. If we have in pituitary extract a preparation that will, as it seems to do, act directly upon the musculature of the vessels, making them contract without exhausting the reserve energy of the vasomotor centers, stimulating the heart without drawing too strongly upon its reserve energy; that will act upon the musculature of the intestinal tract, stimulating these muscles and causing peristalsis to be generated, thus ridding the intestines of the toxic material that has accumulated (accompanied by the development of millions upon millions of bacteria), then we have a remedy from which we can hope for a great deal in the future, especially in the treatment of post-operative conditions. An encouraging feature is the fact that this preparation is different from a great many other agents which act best upon the normal structures, while, on the other hand, we get the best effects from pituitary extract where we have an atonic condition of the structures.

Bernard J. O'Connor: I have had some little experience with pituitary extract in cases of menorrhagia occurring about the close of the menstrual life, often very persistent and profuse without any local inflammatory condition of any kind. In two such cases almost perfect relief was obtained from the use of pituitrin. Recently I had a case of this kind in which pituitrin, every six hours for three days, failed to produce any effect. Curretage was followed by relief for about six weeks, but it was finally necessary to remove the uterus. No pathological condition could be detected in the uterus at that time.

I thoroughly agree with the essayist and Dr. Allen in regard to the influence of pituitary ex-

tract upon the musculature of the blood vessels and intestines. I believe it has more influence upon the involuntary muscles throughout the body than upon the nerve or other centers.

F. T. Fort: I have enjoyed this paper as much or more than any I have heard read before this society. If I have a therapeutic hobby it is pituitary extract. In the past three years I do not believe I have seen a case of shock, either traumatic or surgical, in which I have not used pituitary extract. As staff surgeon at the City Hospital, upon entering upon my duties I see that a supply of pituitary extract is ordered, and for two years I have not had a death at the City Hospital. Of course I do not attribute this fact entirely to the use of pituitary extract, but I am certain that it has saved some lives.

I think it is one of the most reliable sheet-anchors we have in the treatment of post-operative conditions which require something to overcome the shock—almost death-like condition of these patients. In cases where there has been loss of blood, plus shock, I give saline intravenously and immediately after taking the patient from the operating table I begin the use of pituitary extract, giving it every two to four hours as indications require. I sometimes supplement this by the administration of adrenalin. I believe it is better in conditions of shock than any other therapeutic agent we have. It seems to slow the afferent impulses that are being transmitted from the site of the trauma or operation. In that way the shock is shortened and the patient is tided over a period in which death would likely occur without the use of pituitary extract.

I have never used this agent in obstetrical cases, but after using it in from 50 to 100 traumatic and surgical cases I feel that I can vouch for its efficiency.

Harry J. Phillips: I would like to speak to the standpoint of the gynecologist and obstetrician. It seems to me that this agent reaches its highest point of efficiency in obstetrical cases. It can be used with safety in any stage of labor, and especially in the second stage when the os is dilated and the membranes ruptured. It can also be used with safety in those cases where there is no anatomical deformity, and you can save two or three hours that would otherwise be spent at the bedside of the patient. The use of pituitrin or pituitary extract, will bring on hard, steady pains that will lead to an early termination of the labor.

Pituitary extract also plays a very important part in gynecology. In menorrhagia and kindred troubles, caused by inflammatory conditions of the uterus or its adnexa, it can be used with very satisfactory results. I have used it quite a few times in my practice and I feel that it has great therapeutic value. I have never used it, to any extent, for its diuretic effect, nor in shock, but in obstetrical cases I can recommend

it to the younger men, especially where one is anxious to carry the labor through to termination as rapidly as possible and get away from the bedside, thereby saving two or three hours' time.

The paper is a very comprehensive one. The essayist has gone into the subject very thoroughly, and I am sure we have all enjoyed it. I wish to thank the doctor for his paper.

Albro L. Parsons: I have been waiting patiently to hear some one say something about the effect of the anterior portion of the pituitary gland upon metabolism. As Dr. Askenstedt stated, the anterior portion of the pituitary gland and the thyroid gland are analogous in structure. I have had under observation a case of hypothyroidism in a child who came under my care when she was twelve years old. The use of thyroid extract did not produce the results I had hoped for, and I decided to use an extract of the anterior portion of the pituitary gland if it could be obtained. I therefore wrote to several pharmaceutical houses that make animal extracts, and I was informed by each of them that they did not make such an extract. Upon looking up the literature I did not find that any encouraging results had been obtained from it. Of course, my search has not been nearly so thorough as that made by Dr. Simpson. He mentioned two men who claim to have obtained good results from an extract of the anterior portion of the gland in the way of increasing metabolism, and increasing the growth after a period of stunted growth. I see no reason why we should not use it. The anterior portion of the gland is so exactly similar to the thyroid gland that I should think it would supply a very great need.

I hope the essayist, in closing, will tell us more about how he administered this agent, with particular reference to whether it may be given by the mouth, or whether it must be given hypodermatically or intravenously. There seems to be some question as to whether or not any results are obtained from administration by the mouth.

Edward Speidel: Notwithstanding Dr. Phillips' advice to the younger men in regard to the use of pituitrin in obstetrical cases, I would like to caution them, as well as the older men, to be very careful how they use it in these cases. When used at the end of the second stage of labor, it acts very quickly, usually in about three minutes, and unless the chloroform is ready so that we can quickly get the patient under control, a very badly lacerated perineum may be the result. This statement is based upon my experience in two cases that I had recently. We all know and dread the large, heavy primipara. Whenever I get a primipara who weighs more than 150 pounds I know I am going to have a hard time. During the month of August I had such a case, and I worked with it from two o'clock in the morning until eight o'clock at night, making very little progress. As is my custom

in such cases, I gave the patient an hypodermic of morphin. Two hours later the cervix was completely dilated, although it had dilated only about one-third previously. The membranes were ruptured and the patient brought the head down on the perineum and there it stayed. I gave her ten grains of quinin and repeated it twenty minutes later, without any effect. Then, having some pituitrin with me, I gave her an injection, and I am satisfied that it was scarcely three minutes until she began to have hard pains. As is my custom, I delayed the labor, using chloroform, and finally succeeded in delivering the woman of a fourteen-pound baby—the largest living baby I have ever delivered—without laceration of the perineum.

A great many contributions have been made to recent literature in regard to the use of pituitrin in pregnancy, in labor and in the lying-in-period. The September number of the American Journal of Obstetrics and Diseases of Women and Children contains a very excellent article on this subject, in which the author arrives at the following conclusions:

In a number of cases in which abortion was indicated prior to the third month, it was found that repeated injections of pituitrin had no effect. Furthermore, it was found that, in order to induce premature labor after the sixth month, it was necessary, in addition to the injection of pituitrin, to introduce a hydrostatic pack or a bougie into the uterus. At full term, in the first stage of labor, pituitrin should not be used unless the cervix is dilated to the width of three fingers, and then only in cases of uterine inertia. If used before the cervix has dilated to the point mentioned the labor will simply be delayed after the effect has worn off. Its use is also indicated in the second stage of labor, but the best results are obtained in the perineal stage, when the head has come down on the perineum and is making no further progress. Administered at this time, it will often save the use of forceps. However, as I have previously stated, we must be careful to have the chloroform ready so as to be able to retard the expulsion of the head and prevent laceration of the perineum. In the third stage is where the difference between pituitrin and ergot becomes apparent. Pituitrin induces intermitten contractions of the uterus, while ergot causes tonic contractions. Therefore, it is claimed that ergot is better than pituitrin in post-partum hemorrhage. However, in a case of this kind, where a prompt effect is desired, a hypodermic of pituitrin should be given in addition to the administration of ergot.

Because of its effect upon the blood pressure, pituitrin should not be used in cases where there is a pressure of 150 to begin with. Consequently, it should never be administered in the toxemia of pregnancy.

In Cesarean section pituitrin should not be given until after the sutures have been placed in

the uterus, as the effect of the agent is so prompt as to render the introduction of sutures difficult. In the article mentioned the author reports one case in which contraction was so prompt that the sutures in the uterus could not be placed accurately.

One disadvantage in the use of new remedies such as this is that in the beginning they are recommended for practically every condition, and I think it is a wise plan to be exceedingly careful in the use of new remedies until a larger experience with them has demonstrated their proper sphere.

Virgil E Simpson, (Closing): Those who know me best will scarcely credit the idea that I hold a brief for any drug as a panacea for all the ills that human flesh is heir to. I have endeavored, in the presentation of this subject, to give the conclusions of investigators, based on experiments upon both the lower animals and the human species; the deductions are to be drawn by yourselves. I would have liked to have illustrated the paper with some experimental work, such as I presented in connection with an article on suprarenal gland, read before this society some time ago, but on account of the slow action of the drug it would have consumed too much of your time. Furthermore, it is exceedingly difficult to transport the necessary apparatus and conduct such experiments in a satisfactory manner anywhere outside of a laboratory.

If Dr. Askenstedt had paid a little closer attention to the paper, he would have noticed that I called attention to the danger of administering this agent in cases where there is an already high blood tension.

Referring to another portion of Dr. Askenstedt's discussion, I do not believe that results will be obtained from pituitary extract when administered by the mouth. This is also true of suprarenal gland. If we expect to secure results from either of these agents, they must be given intravenously, intraarterially, or perhaps subcutaneously. The active principles of these glands seem to be disintegrated by the fluids in the stomach, and we do not get the desired effect.

Answering Dr. Parsons, I will say that the administration of the whole gland structure, over a long period of time, seems to have an influence on metabolism. If Dr. Parsons desires to use an extract of the anterior portion of the gland, I would suggest that he make his own extract. No pharmaceutical house makes an extract of the anterior lobe as distinguished from the posterior lobe, perhaps because the necessity for its administration has not been appreciated.

I wish to thank the members of the society for the patience they have shown and the interest they have manifested.

POSTURE IN THE ADOLESCENT PERIOD.

By JNO. D. TRAWICK, Louisville.

In a study of the development of the child, one finds points of varying interest at every stage. From the pink bit of new-born helplessness through the first-tooth stage, along the uneven path of the first steps into the confusing maze of learning to talk, up to the first buds of character formation—at every point thus far, his weakness cries aloud for affection and care. The answer ought to be in the fullest protection, the absolute shielding from every sort of mental, moral and physical strain. He is in no condition to bear burdens, his principal work should be in *being formed right*, in getting a straight back and big lungs, a strong heart and a clear mind, in building the foundations for such a nervous constitution that will, among other requirements be capable of elaborating a moral sense that will point him straight.

At five to six years we find him in possibly the most plastic stage of his existence. Whatever goes into his moral fibre now is apt to leave a permanent color in the matured character. Likewise any influence that profoundly effects his physical nature is apt to leave its permanent imprint.

Prior to this age he was merely a mass of potentialities, the most neutral of creatures, whose functions were largely reflex, or automatic. Now we find him learning some new fact every hour, unconsciously incorporating into his character the essential features of his environment.

The problem of the growth of the child has been from the beginning finally one of *nutrition*, in the broadest sense. Whatever makes for the fullest development of the cells is properly included in this term. Every ounce of assimilated nourishment counts; every small bit of wasted energy has its telling effect. Each element in the little body is calling for its particular sort of nourishment. As this need for nourishment increases progressively, so the danger of partial tissue poverty increases.

Let it be kept in mind that in using the term "nourishment," we are referring to more than the gastric function, to more than mere physiological tissue building from assimilated food. When we realize that nutrition means "*all the circumstances of life which effect tissue change*," one comes to feel that no influence is entirely out of its limits. Those disturbances of nutrition which result in physical deformities leave their mark so plainly that they are known and freely discussed.

Mental depression may likewise be left by impaired nutrition. They produce deformities quite as frequently, though we call them

by different names. Social position, duration, manner of occurrence, all determine the term, but we speak of a "child criminal," "an eccentric person," a character that is "weak," or "rash," or "perverse," and by many other like terms designate the results of impaired cell nutrition.

Wrong methods of feeding, of rest, of amusement, of occupation, are some of the elements that help to make a child one-sided, or deficient—a nervous child. It would be interesting, may be profitable to digress just at this point, to inquire into the causes of many of the so-called nervous diseases of childhood, also to picture some of the results, and show how the child is in more senses than one, truly the father of the man, in that what may be having its expression now in the child leaves the permanent mark to appear forever in the matured character.

It is not too much to say in passing that subject, that such nervous children are at once the promise and the danger of the next generation. All the permanent interests of the man have their origin or become greatly emphasized at this age—six to eight—and if any given interest is lacking now it is very unlikely to exist in the mature man.

Nutrition in fact in the child is almost the only part of him after all that is susceptible of cultivation. A fairly important part of each person is born in a certain state without the possibility of change, and an attempt to influence that, would be about as feasible as trying to civilize a remote ancestor. But there remains that part of the person, which we say is susceptible to environment, that must now be effected, or remain forever uncultivated, that is, unenriched.

As our child develops into that period from ten to fourteen years of age, we see nature "making her last great struggle to be generic." As fascinating as a study of adolescence in its psychologic phases, might be, we must pass on to a particular feature and lay our whole energy there. If there has been any failure to cultivate the highest state above all for the deficiency to be recognized, for there can be no disputing the law, that *outside of his own business, the ideas gained by a man at this developmental stage, from 14 say to 25, are practically the only ideas he shall have in his life. He cannot get anything new, for after this, the power of assimilation of the new is gone. The channels are set and the mental process becomes concentrated upon the specialty of that individual career.*

Just as these facts are true of the mental, so do they hold good in the physical development. Every advantage must now be taken of the results of nutritional cultivation in the earlier periods, the good being conserved and

the deficient brought up to as near a normal standard as can be.

In this period of adolescence, call it puberty, junior adolescence, transitional stage, or whatever you may, what should interest us as physicians most, is to see that there is a minimum of wear upon the finely adjusted mechanism of the youth just coming over the horizon of his career, for wear means waste, means fatigue and fatigue is destructive to nerve cells and vital force.

One begins now to see why there should be shown no sympathy for the vicious and misleading doctrine implied in the advice so often heard, in case of so-called minor illness, "just let him alone, that is to be expected, he will outgrow it." On the other hand we have so little patience with over-indulgence, pampering in the training of the adolescent.

It is just as important for the expert in diseases of childhood to incorporate into his ideas for the development and maintenance of a high standard of efficiency, a scheme of general observation of the entire mental, physical and psychological character of the child as it is to develop a scheme for proper feeding, or for the care of the nose and throat.

We are part of a new era that is demanding conservation of our child life, the nation's life. Who has a better right to lead in the cause, indeed upon whom else does the responsibility for leadership rest with greater weight than upon the earnest physician whose heritage it is to know the rights of the child, and to instruct the fathers and mothers of this, even of the next generation, in this greatest cause—the conservation of a race. Truly says Richard Cabot, "It is good to make a living, but infinitely more desirable to make a life."

What the phenomena of adolescence may be in any given individual depends largely upon the person's general health, education, hereditary tendencies, temperament, and the like. Since obviously this is too great a variety of factors to allow for detailed investigation now, it is well to observe a few, and stress their importance. We must refer you to works on pedagogy or to more technical writings for the psychology of the period. This is our opportunity to stress a few physical facts not so frequently written about.

The close observer will notice that at this period there will develop peculiarities of poise of body, aside from the easily explainable awkwardness of the youth, when it is easier for him to fall over a chair than to go around it,—a period nevertheless that we are not disposed to hold up for ridicule. A study of this irregular posture will show that it is incompatible with the fullest unhampered development of the organs involved. In calling attention to posture, we are in danger of leaving

the realm of the practical, if we fail to apply the strictest anatomical and physiological principles to our investigations.

If ever in the process of the growth of the child there can be one time more essential than another, that he have room for full expansion of his lungs, it is in this early adolescent period. You know how the physical changes are taking place, how the heart is enlarging, how the blood-vessels themselves become one-third larger than in early childhood, how the convolutions of the brain are unfolding, the skin becoming more sensitive, the bone-structures are settling into their maturer fixedness, how the intruding tides of Being sweep the real boy so often from pinnacle to peak. The heart needs to be unhampered, the diaphragm free, the abdominal viscera encouraged to their fullest functioning.

This brings us then to consider in detail this feature of the developmental stage of youth, from a very practical standpoint. This patient is brought to us with the statement that he seems so tired on being awakened in the morning. He eats his breakfast mincingly, is off with indifference, lacking the buoyant spirits of naturally optimistic youth. He tires easily, is indifferent in play, and easily shows fatigue. Frequently complains of pains in the abdomen, bilious attacks, and suppurative, in day stool, of appendiceal trouble may be aroused. In the absence of more definite symptoms, and should our investigation stop here, as is too frequently the case the child might be sent away with a tonic, and instructions to get plenty of fresh air, etc., etc., and report back in two or three weeks.

But let this patient be undressed entirely, and even the most untaught observer will see—as one mother remarked, “I don’t know how to tell it, but I see that there is something wrong.” The head and cervical spine are thrown forward, the shoulders droop with a marked forward sag, the scapulae project outward and back from their normal close relationship to the spine. The sternum is depressed so that it is in almost a perpendicular, from ensiform to clavicular notch. The thorax is flattened from before backward, there is a peculiar downward droop to the ribs, with a distinct depression in the upper abdomen, like a fold or furrow, around the hypochondrium.

The abdominal organs are thus naturally forced downward, for the diaphragm is allowed to fall anteriorly, giving the liver room to drop several inches. The whole visceral load seems to be carried by the lower half of the abdominal wall. In this attitude of weakness, or fatigue, the axis of the abdominal cavity is made to more nearly approach the axis of the pelvis, so that the abdominal viscera nat-

urally drop unimpeded into the pelvic bowl. There is an increase in the upper dorsal curve, with a flattening and downward tipping of the pelvis. Think what effect this attitude is bound to have upon the Y ligament. When the body is held erect this ligament is naturally tense, but with the tilting of the pelvis downward and backward since the ligament cannot yield, the thigh must flex and inevitably the knees must show the same effect, giving us the so-called “sprung knees.” Following on down, one finds in nearly every instance that the arches of the feet are depressed or flattened, with a decided valgus, which may be more noticeable on one side than the other. The mere attempted correction of flat foot takes on in the light of these disclosures much more than a strictly local significance, and the failure to observe this general relationship of a local manifestation to a general defect, accounts many times for the failure of well intentioned “arch supports.” With such a faulty poise as this how can nature do her best? Unfortunately, her tendency unassisted, is to increase this attitude of fatigue as the individual grows to maturity. How can there be efficiency, out of such strain as this. Contrast this with the body of one erect and well-poised, where there must be the greatest amount of efficiency or energy whatever function may be required of the individual.

Remember we are speaking of the individual at the period most crucial in his development. Conservation of energy, not waste, efficiency, not inactivity must be the rule, else the growth must be defective, and the development irretrievably impaired. We can grow old but once. Compare the two positions, the erect well-poised, with the drooping, sagging posture of general ptosis, and it is not difficult to decide in which attitude “the spirit of the individual is most apt its greatest potential.”

Any departure from the correct attitude of well-poised balance, must mean dissipation of muscle and nerve energy, must mean body waste. “How unfair the problem of the struggle for existence becomes when in addition to the regular work of the body it is necessary to expend a considerable portion of energy in overcoming the strain of such imperfect posture.” In the sum-total of effort in maturity of a single individual such as this, here pictured, how much greater must have been the total efficiency had the energy been used in accomplishment of the things that count in life, that was wasted in the unconscious friction of mal-adjustment, faulty alignment, incorrect poise.

So common is this type becoming that one is beginning to question as to whether its prevalence is due to the fact of recognition, or if there can be a relationship of cause and effect. At any rate it is true that the type is fairly

constant in these mal-nourished children, but since a large percentage of all the disfigurements which accrue to the mature body and character have their origin in persistent violation, during adolescence, of one or all the demands for proper nourishment, in its comprehensive sense, we are calling loudly for a closer study of the growing child.

Sometimes the feet first attract attention, sometimes the round shoulders with generally bad carriage, sometimes the statement of generally poor condition of the child. We have seen an increasing number of cases, in which poor digestion, some in which abdominal pains were the symptoms for which medical advice was sought. It is easy to see how some one or more organs can be so interfered with by all the bad effects that can accrue, that it is not surprising there should be so great a variety of expressions in the symptoms.

Certain it is that many of the symptoms mentioned disappear when the general principal of treatment of the mal-poise is applied, while heretofore, attention alone to the symptom for which relief was sought, resulted in only partial and temporary benefit. How much permanent good will be gained from the mere treatment of so-called "intestinal indigestion," in these children, if we fail to ascertain that general abdominal ptosis exists, with consequent crippling of function of practically all the viscera.

In considering the treatment, one cannot do better than be guided by Goldthwait, of Boston, who has done more, probably than any other American orthopedist, both in the investigation and treatment of these conditions. He says, in speaking particularly of the visceral ptosis in children, "One does not expect in the treatment to be able to restore the normal visceral supports, but it is not unreasonable to expect that if the condition can by recognition in childhood be controlled, so that it does not increase, that the moderately good nutrition and vitality, which one expects to find in the early years of these children, can be preserved. Whether the special feature for which the child is brought, be feet, or round shoulders, weak knees, or relaxed sacro-iliac joints, whether the condition be medical with poor or irregular appetite, with repeated "bilious" attacks, with frequent clay colored stools, or with simply general mal-nutrition, a thorough examination should be made to determine the fundamental cause of the difficulty.

If these symptoms should all exist, our treatment does not consist in simply doing that which may be required for the local part, but should at the same time be aimed to control the primary lesion. In doing this it is possible that if the body is properly poised and the viscera properly supported, that the

undesired position of the feet or the weakness of the other parts, may be entirely corrected, by no other measure, since it then becomes possible for the parts to work rightly.

Special diets, stomach washings, tonics, may all have their place, but it is reasonable to expect that if the viscera can be properly supported and the body held erect, these measures will be more efficacious, while at times the use of the supports alone may result in such improvement of the functions of the various impaired organs, that little else may be required."

To recapitulate. In the sum total of effort in maturity of a single individual, such as is here pictured, how much greater would have been the total efficiency had the energy been used in accomplishment of the things of life, that was wasted in the unconscious friction of mal-adjustment, faulty alignment, incorrect poise.

From the beginning the problem of the growth of the child is one of nutrition in the broadest sense. Faulty methods of nutrition may result in deformities both of physical and mental nature. There is a point in the formation of character at the adolescent period, when permanent moulding is taking place. After this time, whatever may be lacking will hardly ever be supplied.

Fatigue results in waste and a general observation of the child, mental, moral, and physical, should be the part of every physician. Since faulty posture, results in expenditure of energy that should be directed to growth, it is vital to correct this at the adolescent period.

The type of mal-poise referred to is common, and concerns children particularly who are ill-nourished.

The steps for correction of the irregular poise must be based on practical rules depending on anatomical and physiological relationships.

DISCUSSION.

Harry J. Phillips: This subject is a very unusual, but nevertheless a very vital one. We have all heard the old saying that "the child is father to the man," and this is true not only morally but physically. Every child, during the adolescent period, receives impressions that will last possibly throughout its entire life. The attempts which have been made in recent years to better the conditions in the tenement districts of our larger cities have done a great deal of good, many of these children being benefited morally, hygienically and physically. I would urge every practitioner, especially those who do obstetrics, to not fail to give every child that comes before you a most careful examination. We should not stop at a superficial examination, but should examine carefully into every organ in the child's body insofar as we can. Not only should the child's throat and eyes be looked after, but he should be examined from head to foot in order to determine whether or not there is any physical deformity that needs correction. I treat a good many children, and I am interested in anything that will benefit them.

The treatment, of course, is that which tends to develop the muscular power of the child—fresh air, good food, hygienic surroundings, and calisthenics. If the general rules laid down by Dr. Trawick are followed, they cannot fail to bring about beneficial results.

So far as the morals of these children are concerned, that is something over which the physician has very little control, because, as a rule, we have no control over the child's environments, nor over those with whom he is thrown into daily contact. If the child resides in the slums, amid surroundings that are far from hygienic, the result will be very unsatisfactory. As stated, however, the various women's clubs and organizations are constantly endeavoring to better such conditions in the larger cities.

I have been very much entertained and instructed by the doctor's paper.

Jno. R. Wathen: I think Dr. Trawick struck the keynote when he took the stand that these conditions, in a majority of cases, are congenital. This opens up a big field for surgical consideration. Dr. Clark, of the University of Pennsylvania, recently published a report of his elaborate work in the dissecting-room and the clinic, showing that enteroptosis and visceroptosis are in most instances congenital. Formerly the surgeons here operated upon a great many conditions of the viscera which did not turn out well, the benefit being very slight; in fact, with the possible exception of anchoring the kidney, these cases were almost uniformly failures. The pendulum is now swinging in the other direction and we are letting these patients alone. Dr. Mayo was recently asked the question, "What do you do in cases of enteroptosis and

visceroptosis?" and he answered most emphatically, "I let them alone." I know of a number of cases in Louisville that have been operated upon at different times by various surgeons for visceral conditions, with no benefit. As Dr. Trawick brought out, if we expect to do anything in these cases we must do it in the early years of life, and not wait until later life when they have visceral conditions that are not amenable to surgical treatment. Some method may be evolved in the future by means of which we can benefit these patients, but at the present time the best thing is to let them alone.

Guy P. Grigaby: It seems to me that this is largely a question of eugenics. The father and son presented here to-night are almost identical in type. It appears to me that some law which would prevent the mating of such individuals would be a good thing. It would probably act as a stimulus to them to make better individuals of themselves, morally and physically, if they could be made to realize that they could never marry unless they were physically fit.

Jno. D. Trawick, (Closing): The question of treatment was not more fully gone into because of lack of time. It does not suffice, in these cases, to put them through an indefinite course of diet and calisthenics; there should be some definite object in view. It is a very difficult matter to outline the treatment unless one goes about it deliberately, carefully, and determined not to get out of the realm of the practical and the scientific. We are discussing a subject that is very close to the border line and gets into the sentimental before you know it, and the consideration of questions of this kind should be careful, deliberate and scientific.

The small boy presented here to-night is illustrative of the type of congenital ptosis. I would like to say that earlier in the history of this patient it was perfectly possible to make out the transverse colon lying just above the clavicle.

The second boy was operated upon five years ago for appendicitis, in a very violent stage, and it was possible in this case to see the colon crowded down in the pelvic bowel.

The man also represents the type of congenital ptosis. Truly, as one of the speakers has said, this is a problem of eugenics. If this boy is to be permitted to create his kind later on in life, let him be as fit as possible. It is possible to make something of the boy although he will never be perfect.

As to the direct application of mechanical appliances, this can be done with a great deal of comfort and a certain amount of improvement in nutrition.

I wish to thank the members for the interest they have manifested in the paper and for their discussion.

CLINICAL CASES.

VESICAL PAPILLOMA.

(REPORT OF CASE.)

By E. S. ALLEN, Louisville.

Papilloma is a benign growth resulting from a new growth of epithelial covered papillary processes, arising from the skin or mucous membrane. The seat of occurrence is upon the skin and mucous membranes, in glands, ducts and lining cysts. They take on the type of covering of the structure in which they originate. No matter what the situation of origin, the epithelial structures rest upon a modified connective tissue basis, which is supplied with blood vessels, nerves and lymphatics. There are three varieties of papilloma, according to tissue origin; (1) that type arising from the skin and covered with squamous epithelium, known as the skin wart; (2) that type arising from the mucous surfaces and covered with columnar or stratified squamous epithelium, known as the villous papilloma; and (3) that type originating in glands and cysts and covered with the type of epithelium lining those structures known as the intra-cystic type.

ETIOLOGY.

Papillomata are supposed to have as their etiological factor, irritation, either mechanical, bacteriological, or chemical. This irritation, acting as a stimulation to the epithelial cells, causes a too rapid growth. Very frequently, all that composes the stalk is a very faint stroma and the blood vessels; hence, the ease with which these villi are broken and hemorrhage. The vessels, as a rule, especially in the type occurring in the bladder, have little or no stroma and no muscular coat, which accounts for the very persistent bleeding when one of these villi are broken off.

Mechanical cell division is at a too rapid pace for innervation and specification of function. Cells pile up lawlessly, demanding nutrition and support; hence an hyperplasia of blood vessels and connective tissue. The base, or support, of a papilloma is not a new growth or tumor; it is a stimulation of cellular stroma for support of the rapidly growing epithelial structures.

Papilloma bears this relation to adenoma—it is an adenoma turned wrong side out. A papilloma has the epithelial surface exterior, with the blood supply and basic stroma on the interior. An adenoma has the epithelial structures on the inside, with the stroma and vessels on the outside. The tendency of an adenoma to undergo malignant changes is much greater, probably on account of the

adenoma, as a rule, arising from more highly organized structures.

Villous papilloma occur throughout the mucous surfaces of the body—in the gastro-intestinal tract all the way from the cardiac end of the stomach to the anus, and in frequency according to the distance from the stomach, being most frequent in the rectum.

HISTOLOGY.

There is some slight difference between the villous papilloma and the skin wart. The villi are made up almost entirely of long, slender, epithelial cells which surround and enclose a slender filament of connective tissue, with its blood vessels, as a stalk.

* SYMPTOMS.

A papilloma of the bladder may exist for years without causing any symptoms. Usually hemorrhage is the first symptom which suggests the possibility of a bladder growth. The hemorrhage occurs without apparent cause. Its onset is sudden and it sometimes disappears as suddenly as it comes; it is generally copious. The last urine passed contains more blood than the first. The blood is of a bright red color and contains clots. Such symptoms as these generally point to a bladder tumor. Very frequently fragments of the tumor—small villi broken off—may be found in the urine, which always points to a tumor. The cystoscope will, of course, clear up the diagnosis.

PROGNOSIS.

This is usually unfavorable, even in benign tumors. Infection sooner or later sets in, with cystitis and ulceration. There is always a tendency to malignancy.

The treatment in papilloma is operative.

REPORT OF CASE.

Two months ago I saw Mr. L., in consultation. He gave the following history:

Family History: Negative as to new growths of any type.

Personal History: Has always enjoyed good health except for an attack of lobar pneumonia several years ago. Has never suffered with any venereal trouble. Though 72 years of age, he has never had trouble in urinating. Has never passed any blood. About three days before I saw him he appeared at the office of his family physician with retention, of twelve hours standing. A catheter was introduced and about thirty ounces of bloody urine withdrawn. The physician saw him the following morning and again inserted the catheter, with the same result as on the previous evening. He saw him again in the evening and irrigated the bladder, the urine continuing to come away blood-tinged. The following morning upon intro-

during the catheter, no urine could be obtained. The catheter would become obstructed with blood. I was asked to see the case and found the bladder well distended, being palpable above the pubes. Rectal examination, with the history, pointed to a large blood clot in the bladder, which was the conclusion reached by the family physician.

The patient was operated upon two hours later by suprapubic incision, with evacuation of the clots, disclosing a villous papilloma, about the size of a hen's egg, located near the trigone on the left, about an inch to the outer side of the ureter. The tumor was lifted up by grasping it at its base, which was pedunculated. A purse-string suture of No. 1 twenty-day catgut was placed one-quarter of an inch from the base and the tumor excised with a knife, tying the purse-string and inverting the cut surface of the wound. A drainage tube was placed in the suprapubic wound and a catheter in the urethra. Irrigation at intervals of three hours with boric acid solution was instituted. The patient was placed in a rolling chair in a couple of days and has made a very nice recovery.

DISCUSSION.

O. H. Harris: Blood in the urine may be the result of any one of a number of conditions, and it takes a man of considerable experience to differentiate between them. I remember a case I had some time ago in an elderly man, who had been passing bloody urine for a considerable length of time, and finally his bladder became distended. A surgeon was called to see him, and he did a suprapubic cystotomy, drained him out for a week or ten days, and then removed the tumor.

Blood in the urine after the bladder has become infected is always a very dangerous thing, but before that time the difficulty is to tell where the blood is coming from, and the only diagnostic point of value is sudden and copious hemorrhage. Otherwise, it is necessary to catheterize the ureters in order to tell whether or not the blood is coming from the bladder.

W. C. Dugan: This is a very interesting case. The diagnosis of a villous tumor of the bladder is, as a rule, very easily made, with our present methods of exploration. However, the cystoscope in the hands of an inexperienced man is often very puzzling. A number of years ago, when the cystoscope was first introduced in this city, I had a case in a man who gave a typical history of villous tumor—painless urination, urine uniformly colored, etc. More to gratify my curiosity to look at the case through the cystoscope than anything else, I introduced the instrument and was sure I could see a pedunculated tumor. The case dropped out of my hands for some reason or other and was operated upon, on my diagnosis, by one of my colleagues, who

found no tumor in the bladder. The man died shortly after operation, and, upon postmortem it was found that he had been bleeding from a papilloma in the pelvis of the kidney, and what I had seen was the shadow of the bloody urine coming down through the ureter. Of course that would not happen in the hands of an experienced cystoscopist.

I wish to mention one point in regard to treating inoperable vascular tumors of the bladder. Of course, under ordinary circumstances the operation would not be so hurried as in Dr. Allen's case. In his case there was an emergency that had to be met. A number of years ago I saw a gentleman about 50 years of age, who had bled so long that he was too weak to sit up without swooning. I believe he was the most anemic man I have ever seen. He had been under the care of a number of Louisville doctors. I was then a very young man, and I suppose that, having tried a good many of the older men in town, he had concluded to give the younger ones a chance. I made diagnosis of a villous tumor such as the doctor has shown here. I fancied I could almost see, in my mind's eye, a tumor the size and shape of a ghirking, such as pickles are made of, with a small pedicle. I improvised a Trendelenburg table, opened the man's bladder from above and, to my great astonishment, there was no pedunculated tumor, but a broad villous growth springing from the whole of the trigone, came into view. The man's condition made it impossible to remove such a growth. The base was as large as any other portion of the tumor, occupying a space, I should say, more than an inch across or a circumference of about three inches. This condition is sometimes called a "vesical hemorrhoid." Wishing to do something, but without any hope of relieving the condition, I introduced a T-shaped drainage tube. The next morning before leaving for my home, the patient called me to his bed and asked me what the result of the operation had been. I predicted a fatal termination. I changed the dressing and, to my great astonishment, it was stained with normal urine. The tube was filled with urine and it was not even tinged with blood. It was evident that he was not bleeding and that I had talked too much before changing the dressing. The man got well and never bled from that time until he died a few months ago from pneumonia. Now, why did the hemorrhage stop? Obstetricians say that a contracted uterus cannot bleed. May not the same be true of the bladder? The arrangement of the muscular fibres of the bladder is such that when it contracts it strangles the blood vessels, and I consider that to be the logical explanation of the cessation of bleeding in my case.

You will say: "Well, maybe the tumor did not disappear." In answer to that I will say that I had occasion to open the bladder some six or eight months later to remove a stone formed

around one of the stures and the tumor had entirely disappeared.

I report this case simply to call attention to the method of dealing with inoperable vascular tumors, with broad bases, by means of drainage.

E. S. Allen, (Closing): As stated in the report, I operated upon this man to relieve a blood clot in the bladder, suspecting a malignant condition rather than a benign papilloma. Several years ago I had a similar case of bleeding in which I suspected papilloma, but upon operating found a multiple carcinoma of the bladder. There were fifteen or twenty of what appeared to be little villous papillomata that had undergone carcinomatous degeneration, very much indurated and infiltrated. I put in a drain but this man died in the course of a short time.

CEREBROSPINAL MENINGITIS.

(REPORT OF CASE.)

By DONALD K. CLARK, Louisville.

In this report this evening I have chosen those cases which I consider of the most interest, and which are illustrative of the various types of cerebrospinal meningitis as seen in the late epidemic in this city.

I have taken up the cases individually, touching upon the more important symptoms, the character of the spinal fluid, the amount of serum used, end result, etc. I am not going to take up the treatment in detail, but will say that each case, in addition to the serum, received urotropin in appropriate dosage, as well as various symptomatic remedies.

The clinical diagnosis was confirmed microscopically in each case by Dr. Vernon Robins, of the City Board of Health.

CASE I.

T. M., male, colored, age 8, admitted to the Emergency Hospital, March 2nd, being the first patient received. On examination the patient presented the following symptoms: Slight retraction of head, mild delirium, marked Kernig's sign, hyperesthesia and herpes labialis. A lumbar puncture was then made. The fluid obtained was rather cloudy and under slight pressure. About 40 c.c. of the fluid was then withdrawn and 20 c.c. of the serum administered. This patient made marked improvement after the first dose. In all, he received 80 c.c. of the serum, being discharged March 13th, with recovery complete. This was a very mild case.

CASE II.

L. H., female, white, age 12; admitted to the hospital March 7th. This case presented a very marked retraction of the head, positive Kernig's sign, extreme delirium, marked hyperesthesia, labial herpes, and absolute deaf-

ness. Temperature (axillary) 101.5; pulse 110; respiration 28. A lumbar puncture was immediately made, the fluid withdrawn being very cloudy and under a good deal of pressure. Twenty c.c. of the serum were administered as the initial dose, the patient receiving 120 c.c. of the serum altogether. The patient developed an acute nephritis during the course of the disease. She was discharged from the hospital March 28th, the nephritis having cleared up, but still being absolutely deaf. I was not able to follow the case after she left the hospital.

CASE III.

T. N., male, white, age 28, admitted to the hospital March 16th. This man was employed as a news agent on one of the railroads. During the day he had developed symptoms of the disease and was brought to the hospital late in the day. On admission he complained of intense pain in the back of his head, slight retraction of the head, stiffness of the neck, and some hyperesthesia. The spinal fluid obtained was rather cloudy but under no pressure. Highest temperature was 100 degrees F.; pulse 80; respiration 20, and the lowest 97 degrees, 64, and 18 respectively. This patient received a total of 80 c.c. of the serum. He made an uninterrupted recovery and was discharged March 24th, completely well.

CASE IV.

T. M., male, white, age 43, admitted to the hospital March 16th, profoundly unconscious. He presented marked retraction of the head, Kernig's sign, and later delirium and hyperesthesia. The spinal fluid was very thick and cloudy but not under very much pressure. Highest temperature, pulse and respiration, 101 4-5, 160, and 50 respectively. This patient received, in all, 100 c.c. of serum but grew steadily worse and died March 26th.

CASE V.

A. M., male, white, age 15; admitted March 18th, unconscious. This patient presented marked retraction of the head, Kernig's sign and herpes. The spinal fluid was very cloudy and under marked pressure. The patient had received 20 c.c. of the serum just before being sent to the hospital. This was repeated about 12 hours after admission. He developed a lobar pneumonia almost immediately after admission and died the following day.

CASES VI AND VII.

R. F. and Wm. F., males, white, brothers, aged respectively 3 and 11, admitted March 20th. These cases were practically identical, both having marked retraction of the head, Kernig's sign, herpes and delirium. The younger, in addition, had an internal squint.

The elder complained of double vision, but I think his statements were rather unreliable. The spinal fluid in both of these cases was cloudy but not under pressure. They each received 80 c.c. of the serum and were discharged March 29th, recovery being complete.

CASE VIII.

R. M., male, white, age 18 months; admitted to hospital unconscious. This case presented slight retraction of the head, slight Kernig's sign, unequal pupils, and herpes labialis. The child, in addition, had a marked bronchopneumonia. The spinal fluid was cloudy and not very abundant. I gave the child 20 c.c. of the serum. The child grew progressively worse and died 20 hours after admission. I was unable to determine in this case which of the two conditions was primary.

CASE IX.

T. D., male, white, age 55; admitted to hospital April 1st. This was not a very well-marked case. The patient complained of pain in the back of the head, stiffness of the neck and some retraction of the head, with a slight temperature. Typical diplococci had been found in the spinal fluid prior to his admission. He received his first dose of the serum after he had been in the hospital twelve hours. The spinal fluid was rather cloudy but under no pressure. This patient received, in all, 80 c.c. of the serum, and was discharged April 10th with recovery complete.

CASE X.

L. B., female, white, age 30; admitted April 3rd. This patient was extremely delirious and had all kinds of fantastic hallucinations. She had slight retraction of the head and marked Kernig's sign. The spinal fluid was very cloudy but under no pressure. The patient received 80 c.c. of serum and was discharged April 11th, with complete recovery.

CASE XI.

J. M., male, white, age about 21. This case was one of the fulminating type. The patient's father gave me his history as follows: The patient was sitting at the breakfast table when he gave a sudden start, and putting his hand on the back of his head said he had a sudden intense pain there. Immediate prostration followed, and he was brought to the hospital about 5 p. m. The patient was now intensely delirious, with practically no retraction of the head, and no other symptom of meningitis save vomiting, which did not seem to be of the so-called "projectile type." The appearance of the cerebrospinal fluid was, however, rather characteristic. It was very cloudy, and under enough pressure to cause it to spurt a distance of two or three

feet. Thirty c.c. of the serum were then administered, but the patient died about five hours after admission, approximately eleven hours after the onset of the disease.

CASE XII.

S. G., female, colored, age 32; admitted March 31st. This patient complained of intense headache and nausea. There was slight retraction of the head, rigidity of the neck, herpes and Kernig's sign. The patient was at no time delirious or unconscious. The spinal fluid was slightly cloudy and under a little pressure. This patient received 80 c.c. of the serum, and was discharged nine days later with recovery complete.

These cases cover, I think, the more common types of the disease. I had two of the so-called "dry canals." One case recovered and the other died. I made any number of post mortem punctures, but was never able to obtain any fluid.

DISCUSSION.

Vernon Robins: I wish to speak to one feature of this subject in particular. There is no question that the series of cases treated at the Emergency Hospital demonstrated the efficiency of the anti-meningitis serum. The epidemic that we had here created a great stir, which was, I think, to a large degree unnecessary. Some physicians were, literally speaking, panic-stricken, and they communicated their panic to their patients and succeeded in bringing about a very sad state of affairs. Each year we have quite a large number of deaths from meningitis, most of which are probably of the cerebrospinal type. There have been years in which the total number of deaths from meningitis was considerably larger than during the late epidemic. This year, however, a rather dramatic feature attended the opening of the epidemic. I refer to the two children who were at first supposed to have been poisoned by something they had eaten. Another feature of this epidemic which gave it an unnecessarily serious aspect was the routine examination of the spinal fluid and the employment of the intraspinal treatment, which hitherto had been done rather infrequently if at all. It was necessary for even some of the surgeons to learn how to make a spinal puncture properly. Some of the older surgeons frankly stated that they had never made one and knew nothing about it. Such circumstances, of course, gave rise to a great deal of apprehension at the outset.

The chief object of my discussion to-night is to emphasize the needlessness—indeed, the harmfulness—of the panic with which some of the physicians were seized at the time of this epidemic.

The epidemic was characterized by two types of the disease; (1) that which was rapidly fatal

and (2) that which, although running a severe course, later on became convalescent. The mortality, if I remember correctly, was about 39 per cent.

The outlook for next winter is, perhaps, not entirely satisfactory. The disease is more apt to make its appearance at the close of the winter, but we recognize now, as we did not heretofore, that healthy carriers of the disease are not few in number. This adds to the seriousness of the outlook.

I am very glad indeed to have heard Dr. Clark's paper.

W. A. Jenkins: ' would like to ask one practical question which the doctor's remarks about the dry type of canal brought to my mind.

I should think it would be very easy for adhesions to take place between the inflamed surfaces of the membranes of the spinal canal, and perhaps shut off a certain portion of the cord, although a great deal of fluid might be obtainable above this point. I would like to ask Dr. Clark whether one particular anatomical site is always selected for the puncture.

E. S. Allen: I hardly see how it is possible to have a dry spinal canal in this condition. We know that wherever we have an infection the inflammation creates a disturbance and sufficient toxin is generated to cause Nature to throw out cellular elements and enzymes as protective substances, and in a case of meningitis I can hardly see how, with bacteria present in the canal creating a disturbance and generating toxin, and causing all the typical meningococcal symptoms, we could have a canal with no fluid in it. I can understand how we might have a limited amount of fluid in cases where we have blocking of the canal by the inflamed membranes becoming adherent. Furthermore, the increased intracranial tension caused by this condition would account for the marked pain of which these patients complain. Again, if we withdraw too much fluid from the spinal canal, we have a sudden slapping down of the medulla against the base of the brain, producing an acute anemia, a similar condition to that which is produced when we aspirate the cord in brain tumor.

I would like to mention a case that I saw in consultation. The doctor, after several attempts to make a lumbar puncture, without success, came to the conclusion that he was dealing with a so-called dry canal. Upon introducing the needle further, in a last effort to secure some fluid, the patient moved and the needle was broken off, and I was called to remove the fragment. In doing so I found that the needle, instead of going into the cord, had passed between the lamina just back of the cord and missed it entirely. While I know that Dr. Clark must have become expert in making lumbar puncture, having done so many of them, still this gentleman I speak of had also made quite a number, and we can readily appreciate how easy it is to miss the spinal canal

entirely if the needle be introduced at the wrong angle. In this case he missed the cord probably 1-8 or 1-4 of an inch. Therefore, I believe that, in a good many instances of so-called dry canal, the cord has been missed in making the puncture.

I would like to ask Dr. Robins whether he has ever employed vaccination with meningococcal vaccine as a prophylactic measure. Cases reported in recent literature show that comparatively few persons thus vaccinated develop meningitis, and where the disease does manifest itself, it runs a very mild course.

Vernon Robins: Answering Dr. Allen's question, I will say that we have had no experience whatever in vaccinating against cerebrospinal meningitis.

In regard to the so-called dry canals, we have seen—as you are sure to see in all epidemics of this kind—fluids of various kinds drawn from the spinal canal. The most common type is a very watery fluid with some pus in it, but not infrequently we see a very thick, syrupy material coming from the source of infection. Of course, it is a much easier matter for a fluid of the latter type to become obstructed in its efforts to get to the lower part of the canal, and the ordinary needle will fail to withdraw it. In one case in which we at first failed to get any fluid, by persistent pumping, pulling back on the syringe several times, we finally managed to get a little thick gummy fluid. Therefore, it is clear that if the fluid in any particular case is of the thick, tenacious character, we are not going to be very successful in our efforts to empty the spinal canal.

Donald K. Clark, (Closing): Answering Dr. Jenkins, I will say that we have practically always selected a point between the third and fourth lumbar vertebra for spinal puncture, but in a number of instances where we found it difficult to obtain fluid, we have gone as high as the tenth dorsal, and in one instance in the region of the seventh cervical. I have never seen any bad results from this procedure in any case. Dr. Jenkins' theory about the membranes becoming adherent and closing off the lower part of the canal in some instances, is probably correct. In one case, however, I went up into the canal as far as I could get, and I am satisfied that there was absolutely no fluid in it. I have seen only two dry canals out of 70 to 75 cases.

Ap Morgan Vance: Were any autopsies made?

Donald K. Clark: I did not have any facilities for making autopsies and I do not think any were made.

Just a word in regard to Dr. Allen's remarks about it being an easy matter to miss the canal. In my first few cases I had quite a little difficulty in getting into the canal. Unless we have the patient in the proper position, it is a mighty easy thing to miss the canal. Two methods are recommended; one slightly to the side of the median line and the other directly through the median line. I have had greatest success with the latter

method. I have aspirated a number of cases in which I was unable to get a drop of any kind of fluid, except possibly just a little blood upon pulling the needle back, which I think came from the skin puncture.

EMBRYONIC MIXED TUMOR OF THE KIDNEY.

(REPORT OF CASE.)

By WM. H. WATHEN, Louisville.

Miss B., aged 12 years, was operated upon at St. Anthony's the 9th day of July, for an embryonic mixed tumor of the left kidney. The tumor extended over far to the right side, to the pelvis and to the diaphragm. The case was referred to me by Dr. E. S. Grasser, who was the attending physician of her and her mother, but neither of them had called his attention to any enlargement in the abdomen, and the tumor was observed by him only six days before the operation while making an examination to find a cause why she had had no stool for nearly a week after taking much purgative medicine. The mother had observed for several weeks that the girl's abdomen was enlarging, but did not suspect a tumor. She had but little pain in the abdomen at any time, but for several weeks was unable to get a good bowel movement unless she took an active purgative. She was losing flesh for three months and was not as large or as well developed as the average girl of her age. Her bladder action was about normal, as was the character of the urine as shown in a chemical and microscopic examination. At no time had there been any blood in the urine. For three weeks before she was operated upon she had pains in her legs and could not walk well. This her mother believed to be caused by rheumatism. The tumor was hard, and as it was not attached to the anterior abdominal wall, was movable to a limited degree. The following is the report of the findings of Dr. E. F. Horine in his blood analysis:

Erythrocytes 2,144,000; leucocytes 13,800; polymorphonuclear neutrophils 83.6%; lymphocytes 12.4%; transitional forms 3.7%; eosinophiles not present, basophiles 3%; very few platelets observed.

An incision was made through the left rectus muscle and the tumor well exposed. While there were no attachments to the anterior wall, the tumor had become so adherent to the intestines, the attached descending colon in front of it could not be removed, as is so often the case when there is much delay in operating for embryonic mixed tumors of the kidney. It required large doses of calomel to get bowel movements after the operation, but otherwise she did well and left the hospital in less than two weeks. She continued in the care of

Dr. Grasser and died six weeks after the operation.

Embryonic mixed tumors of the kidney are always in children under 15 years old, and more than 50% in children under the age of 3 years. They nearly always arise in the parenchyma of the kidney, but do not infiltrate the kidney, as other malignant tumors do.

The pathogenesis of these tumors is obscure, but Wilson's theory that the growth is due to inclusions of the myotome and similar structures has received the most support. They are intensely malignant and of rapid growth. The patient seldom lives one year after the diagnosis of the kidney involvement, and 50%, with or without operation, die within six months. They do not cause haematuria in more than 5 to 10% of the cases, because the growth of the tumor is more extrusive, or evasive, and does not often invade the calices or pelvis of the kidney, which hypernephroma, carcinoma and sarcoma nearly always do at some stage of their growth. Embryonic mixed tumors of the kidney are of rapid growth, and may form such attachments to the colon, intestines, and other abdominal viscera, that they are usually inoperable unless treated in the early stages. These tumors were formerly confounded with sarcoma, but it has been shown by modern pathology that sarcoma, carcinoma, or hypernephroma seldom or never develop in the kidney in childhood, and rarely before the age of 20, and such cases reported are clinical and pathological errors.

Embryonic mixed tumors of the kidney are more frequent than all other malignant tumors of the kidney combined, in children under the age of ten years, and hypernephroma of the kidney is five times more frequent between the ages of 20 and 60 years than carcinoma and sarcoma combined. Sarcoma of the kidney was, until ten years ago, believed to be relatively frequent in early childhood, but most of these cases were manifestly embryonic mixed tumors. Rhabdomyonephroma should not be confounded with embryonic mixed tumors of the kidney, for it does not appear in early childhood, is rarely seen, and the history and symptoms are in no sense identical.

Metastasis has been observed in about 20 per cent. of embryonic mixed tumors of the kidney, but it is usual in delayed cases of hypernephromata. Histogenetically and pathologically, hypernephromata may be classified as mesotheliomata developed from embryonic tissue, which while isolated is surrounded by structures developed from similar tissue. This is probably a reason why these tumors develop only in adult life. In Wilson's 34 cases pathologically examined, all appeared

between the ages of 30 and 64 years, and 13 of these between the ages of 50 and 60 years.

DISCUSSION.

Louis Frank: I have enjoyed Dr. Wathen's report very much indeed, but I believe that the differentiation between embryonic mixed tumor and hypernephromata, sarcomata and carcinomata, is rather of academic interest than of actual practical value with respect to the treatment of these conditons. I would like to ask Dr. Wathen to tell us, in closing, in what respect is the similarity between embryonic mixed tumors, hypernephromata and sarcomata so close, histologically, as to make one liable to the errors he speaks of having been made?

Wm. Wathen. (Closing): Answering Dr. Frank's question, I will say that mixed tumors always occur in children, more than 50 per cent before the end of the third year. A very few occur after the sixth year, and probably none in children of 15 years or more, although a few such cases (probably erroneously diagnosed) have been reported. As a rule, the first indication of a mixed tumor is an accidentally observed enlargement of the child's abdomen. There is haematuria in about 6 per cent of cases. They die quickly, 50 per cent within the first six months, whether operated upon or not. They all die within one year, and those cases reported as having lived more than one year after discovery of the tumor were probably erroneously diagnosed. Hypernephromata, on the other hand, never occur in persons under twenty years of age, or at least, under fifteen. They are of slow growth, the patient usually surviving from two to five years after the beginning. In the case I reported to this society in December, the haematuria began five years ago, then disappeared for a while, then recurred, and so on until it finally became almost continuous. Unlike mixed tumors, hypernephromata are not of rapid growth. Practically all cases of hypernephromata have haematuria.

The diagnosis must be made from the history of the case, supplemented, of course, by physical examination. Microscopically, there is not much difference, because both growths very closely resemble in microscopic appearance, a sarcoma. Watson and Cunningham give a very good description of these tumors. The pathology, while not entirely worked out, has been carried on sufficiently to show that both types of growth partake, in their pathological histology, of the character of a sarcoma. Therefore, I claim that probably all cases of sarcoma reported in early childhood are simply cases of mistaken diagnoses, and that they are really embryonic mixed tumors, and I believe this statement will be borne out by future investigation.

A REPORT OF TWO CASES OF NASOPHARYNGEAL POLYPS.

By GAYLORD C. HALL, Louisville.

CASE I.

This case is of interest on account of the mistaken diagnosis and the number of operations the patient was forced to undergo without any relief. The history is as follows: E. E. Von R., age 35, white, male, married. Trouble with the nose had existed for years. The left side was stopped up at all times. On forced inspiration a small volume of air could be obtained, but on expiration the stoppage was absolute. This, it seems, would have been sufficient to have made a diagnosis, though it was apparently not considered seriously in his previous operations, nor by myself during the first operation.

He was operated on first in 1892, in Butte, Montana. The inferior turbinates were cauterized with the galvano-cautery and the tonsils removed. This, however, did not clear up the trouble on the left side of the nose. In fact the patient thought he slowly became worse. Nothing more was done for several years, when the patient consulted an eminent rhinologist of Chicago, who removed the adenoids and snared off the posterior end of the inferior turbinate. These procedures likewise failed to relieve his trouble and the chiseling of a bony spine off the posterior portion of the septum was advised and declined, the patient being about to leave Chicago. He consulted me on October 10, 1907. Examination of the nose showed a thin, narrow nose. Right side of the nose free, turbinate not engorged. Left side of nose apparently free along the inferior turbinate except for a small projection on posterior portion of the septum already referred to. However, it was possible to look beyond this to what was apparently the posterior wall of the naso-pharynx. The middle turbinate on the left side was enlarged and pressed for its whole length against the septum. It was practically impossible for him to blow the left nostril, though a fair amount of air could be taken in on inspiration. An examination of the throat revealed the remains of tonsils now submerged, with diffuse redness over the whole pharynx and a granular condition of the posterior wall. An examination of the naso-pharynx was attempted, but it was impossible to use a mirror, as the slightest attempt caused retching. I therefore refrained from inserting my finger in the naso-pharynx out of consideration for the feelings of the patient, and there is where I made a serious mistake, for I feel that I done so at the time I would have saved the patient an operation and its attendant inconvenience.

He came to have the spine on the septum removed, but I assured him that this could hardly be the sole cause of his difficulty and advised the resection of the middle turbinate.

On October 15th I removed the middle turbinate and the bony spine on the septum with very little trouble and the patient was able to blow his nose at the conclusion with comparative freedom, though not without effort. I was puzzled at the time, but thinking that things would right themselves I did not proceed farther, but packed the nostril as much to prevent adhesions as to control hemorrhage. After twenty-four hours the packing was removed and a long paraffin splint inserted. This of course necessarily prevented very free respiration on that side so that the result of the procedure was in doubt. However, on removal of the splint his condition was very very little if any better than before. After waiting several days with no improvement I again thoroughly cocaineized the nose, on October 26th, for further operative procedure, as I supposed an adhesion between the posterior part of the septum and the inferior turbinate had taken place. Careful inspection of the now shrunken nasal structure failed to reveal any adhesions and I inserted my finger into the naso-pharynx for a possible solution of the difficulty. On the left side my finger encountered a large, smooth, soft mass, the nature of which I was unable to determine, but which was apparently attached to the upper, outer wall of the naso-pharynx. I want to confess that even at this point I did not suspect the large solitary naso-pharyngeal polyp as being the cause and can only plead in extenuation that two other men had likewise failed to discover it. My attention was now directed to the examination of the nose and I now discovered that what I had taken for the posterior wall of the naso-pharynx was the anterior surface of this growth.

The difficulty of examining the naso-pharynx and the fact that the growth moved when the patient said "K" or "enekoo," led me into this error. On passing a thin-bladed instrument through the nose for the purpose of determining the extent of attachment of the growth, it was dislodged and fell into the pharynx and so out of the mouth of the patient, much to his delight and with entire relief of all his symptoms.

The growth was pear-shaped and measured 1x3-4 in. It was evidently freely movable and by its valve-like action completely blocked the left side on expiration, but by falling into the naso-pharynx permitted a small amount of air to pass on inspiration.

The growth had evidently been present for years and should have been discovered long before it was, and I feel that it taught me a lesson that I shall not soon forget.

CASE II.

Mr. J. R. W., July 10th, 1911. Referred to me by Dr. Kiefer. Has had an obstruction in nose for some time, worse on right side. On bending forward or blowing nose hard right side completely closes. On leaning back ward or lying down has a sensation of something dropping backward.

EXAMINATION.

Anterior nares right side, free. Left side obstructed by an angular deflection of septum and corresponding engorgement of turbinate. Sinuses clear.

Examination of naso-pharynx shows the whole right side obstructed by a large pale growth. After shrinking could be seen on floor of nose through anterior nares. Seemed to be attached under posterior end of middle turbinate. Removed under cocaine without hemorrhage.

This growth is larger than the other and flattened on one side. It measures 1 1-4x7-8x 1-2 inches.

The patient had immediate relief of all symptoms and there has been no tendency to recurrence to date.

These cases are in every particular different from the usual polypoid condition in the nose resulting from chronic suppurative of the sinuses. It is my opinion, however, that these growths have their beginning in a suppurative process and while the rest of the membrane recovered the impulse that started growth in the first place is sufficient to carry on the nutrition of the already started polyp.

DISCUSSION.

J. M. Ray: My experience is that these cases are not very uncommon. I frequently see cases of single polyps growing from the under surface of the middle turbinal fossa and back-tracking into the naso-pharynx, and by their own weight filling up with serum and producing pedunculated masses in the naso-pharynx. I operated on one of these cases last Saturday; it took only a few minutes to do it. In this case the mass filled the whole naso-pharynx. When I cut off the pedicle the mass dropped into his mouth and he spit it out.

In my opinion, a single nasal polyp may occur without the presence of accessory sinus disease. However, in practically every case of multiple polyp, where the whole under surface of the middle turbinal seems to be undergoing polypoid degeneration there is accessory sinus disease. Which is the cause and which is the effect, we do not know.

As I said, in my experience, single nasal polyp is not an uncommon condition. I think I have five or six in my office which have been collected in the last two or three years. However, I do be-

lieve that, when they grow in the manner outlined by Dr. Hall, they are sometimes overlooked. The man I operated upon last week had been seen by a nose and throat doctor in one of the smaller towns of this State who had failed to detect the growth. However, close attention to the points brought out by Dr. Hall in his report will usually make the diagnosis quite easy.

The easiest way to remove these growths is, not by means of a snare, because it is difficult to get the snare wire back into the naso-pharynx and around the growth. After thoroughly cocaineizing the nose, I take a plain hook and move the growth up and down until I find out where the pedicle is; then slip the hook around the pedicle, give it a quick jerk and the growth drops down into the throat. There is practically no hemorrhage.

These growths are not likely to recur but they sometimes do.

I used the Holmes pharyngoscope on this case last Saturday but I do not think it helped me any: I can do just as well by taking an applicator and feeling the growth and moving it around.

S. G. Dabney: I agree with Dr. Ray that this condition is not rare. Just a word or two about the diagnosis. I think that, in the very great majority of cases, we can make satisfactory examination of the naso-pharynx by means of the ordinary posterior rhinoscopic mirror if we will cocaineize the posterior wall of the pharynx. Personally, I use with a great deal of satisfaction the White palate retractor and have found it an exceptional occurrence not to be able to pull the soft palate forward. I put a ten per cent. solution of cocaine on the pharynx and soft palate, drawing the soft palate forward with the retractor (the lips being closed, but not the teeth until the patient learns to breathe easy and tolerate the instrument) and teaching the patient to breathe quietly, and I find it very rare not to be able to obtain a good view of the naso-pharynx.

The subjective diagnostic points have already been alluded to. Very frequently the growth does not bob up and down; I have seen a good many so tightly wedged that they could move very little indeed.

I have seen two or three cases which presented some unusual features that might possibly be worth mentioning. In one case that I saw, in a child, there was a large post-nasal polyp on each side, which is a very unusual occurrence in children. My first diagnosis would have been adenoid growth, but it proved to be a polypoid growth, hanging back in the post-nasal space.

One case that I do not think I will ever forget was one that was sent to Dr. Dugan many years ago, and he was kind enough to refer the man to me. This was a colored man, between 35 and 40 years of age. When I saw him he was in the last stage of emaciation and was walking with a cane. He had cachexia of the

type that we usually see in far advanced malignant disease. I looked into the man's mouth and my first impression was that he had two tongues. He had a large red mass lying on top of the tongue which looked for all the world like a second tongue. Then this mass disappeared dropping back into his throat, and for a time he could talk a little better. He gave a history that something had been growing in his throat for years. Sometime before he had begun to vomit, and had vomited almost everything he ate every day. It was this that had caused him to become so weak and emaciated. I examined his throat a little more closely and found a very firm mass hanging down in the oesophagus. Every now and then he would vomit it up and it would lay on his tongue for a little while and then drop back. I have never seen a case like it. The mass was very firm and vascular looking, and I was afraid to remove it by ordinary methods. I used an electro-cautery snare and burned it off. If my memory serves me correctly it was nine inches long.

I have rarely seen these growths recur. Like Dr. Ray, I think a single nasal polyp does not usually indicate disease of the accessory sinuses, but multiple polypoid growths about the nose itself generally mean ethmoid disease.

W. C. Dugan: Just a few words in regard to the case mentioned by Dr. Dabney: A good many years ago when I was holding clinics at the City Hospital, Dr. Stedman called me up and asked me if I would like to have a case of sarcoma of the tongue for my clinic. I had already made up my clinic for the day, but as the man had come here from the country, I told him I would remove the tongue. He sent the patient up to me, and the question came up as to whether or not the case was an operable one. The man seemed to be in an advanced stage of malignant disease, and could not talk. Unfortunately, he did not swallow the growth during my examination. I made a careful inspection of the neck to see whether or not there was any lymphatic involvement, to enable me to decide whether or not to attempt to remove the tongue. I never in my life saw such distress as was evident on this man's face. Very fortunately for the patient, during my efforts to ascertain how far the growth extended from the surrounding structures, I chanced to spy the tip of the tongue, and the diagnosis was then very easy. I sent him to Dr. Dabney who has told you the further history of the case.

This man weighed, normally, about 200 pounds, and he had dwindled down until he was the mere shadow of his former self and could hardly walk. I shall never forget the case, nor the look of distress upon this man's face when I saw him.

Gaylord C. Hall, (Closing): I wish to say again that I did not show these cases as medical curiosities, but in order to bring out the fact that we are very apt to make mistakes with re-

spect to the early diagnosis of this condition. As to the frequency with which these cases occur, I can only hope that when my limited experience shall have reached the proportions of that of Dr. Ray or Dr. Dabney, they will be frequent in my practice also. At present they are rather rare.

The removal of these growths presented no particular difficulties. In each instance I removed the growth with the little hook knife that we usually use for removal of the turbinal. In neither case has there ever been a sign of recurrence.

In regard to the site from which these tumors most frequently grow, I did not make the statement in my report that they grow from the nasopharynx. In each of the cases reported, the growth ran under the shelving edge of the posterior portion of the middle turbinal, and probably had its inception in some infection of the posterior ethmoidal cells.

Regarding the naso-pharyngoscope, I think that in the first case this would have helped me materially. This man was a peculiar individual. The minute one would approach him with a tongue depressor, he would begin to retch, in spite of the application of cocaine and instructions in regard to deep breathing. After spending one or two afternoons in a vain attempt to get a view of his naso-pharynx, I had to give it up. There are such cases. They are rare, it is true, but every once in a while we run across one of them. If, in the first case reported, I had been able to obtain a view of the naso-pharynx, or if I had introduced my finger, I am sure I would have had no difficulty in making the diagnosis.

MEDICAL PROGRESS

DEPARTMENT OF GENERAL SURGERY.

By ALBRO L. PARSONS, GUY P. GRIGSBY,
Louisville.

I.—BISMUTH PASTE USED IN SURGERY.

E. G. Beck, *New York State Journal of Medicine*, August, 1912.

Beck attributes the unsuccessful results that sometimes follow the use of this remedy, to the fact that a few cardinal principles are not followed in its administration.

He believes that if the following rules are adhered to, the unsuccessful cases will be less frequent:

1. After a sinus has been injected with the paste, a radiograph should be taken before any operative procedure; this will exclude operation on inoperable cases.

2. Do not use single plates but stereoscopic radiographs for diagnostic purposes.

3. Errors are often made in too frequent injections of the paste. After the first in-

jection a week should elapse. It is important to note the discharge at the end of that time; if it continues purulent repeat the injection; if it has changed to a serous one it should be deferred.

4. It should not be used in very acute cases.

5. Where a foreign body is present, a piece of diseased tissue, or a sequestrum is at the bottom, the use of the paste will be without a favorable result.

6. Fill every part of the sinus tract at the one time, or else it will do no good.

7. If several openings exist inject in one only and when the paste begins to emerge from the other openings stop them with the tips of the fingers so that the paste will be forced into all of the tracts.

Keep in mind the fact that bismuth poisoning is a possibility. If the rules are carefully observed this will be avoided. Watch for the appearance of blue ulceration of the gums, diarrhea, and emaciation. If poisoning does occur it can be stopped by the following:

Wash the cavity of the sinus with warm olive oil. Fill the cavity with the same substance and retain it for twenty-four hours and withdraw it with suction. Wash the sinus daily with olive oil until the symptoms have disappeared.

The use of large quantities of the paste to fill cavities of unusual size is often the cause of poisoning.

Scraping the walls is to be condemned as it will only increase the symptoms.

The blue line alone does not mean poisoning but shows the systemic effect, and is a warning to discontinue the injections.

G. P. G.

II.—THE TALMA OPERATION FOR CIRRHOSIS OF THE LIVER.

Surgery, Gynecology, and Obstetrics, September, 1912.

Under the above title Edgar A. Vander Veer, gives the history, results of the operation, and reports three cases.

The results of operation in the hands of the most prominent surgeons of this country, as collected by H. H. Grant, of Louisville, are as follows:

Seventeen, or 11% cured after three years. Seventeen, or 11% died as result of the operation.

Sixty-four, or 44% are reported as improved.

Thirty-two, or 22% are reported as unimproved.

Vanderveer observes that formerly only the hopeless and most desperate cases were subjected to the operation and as a natural consequence with poor results.

There have been several successful cases re-

ported in the past few years, that have again revived an interest in the operation. Despite the fact that the operation does not seem rational in theory, the duration of its trial and the success attending its employment, would recommend it as the operation of choice in dealing with this condition. He would urge that the profession should be educated up to the fact that the distressing symptom of ascites of the liver can be greatly ameliorated, if not cured, by operation, and that the earlier the patient reaches the surgeon the more favorable the result.

The operation is more successful in syphilitic and the alcoholic cirrhosis, than in the other forms, because these cases yield best to medical treatment after the stasis in the liver has been relieved and the liver cells can have the opportunity to regenerate.

Of the three cases reports; one died as a result of the operation; the other two were successful. It is interesting to note that one of the cases so regained his health that he was accepted for life insurance by two different companies.

He advises a median incision below the umbilicus, as this gives a good view of the abdominal content, and if a mistake in the diagnosis has been made it is easily detected. At the same time the liver and the spleen can be palpated. It allows the attaching of a greater surface of the omentum through the one incision. He condemns the practice, as in the Talma technic of the operation, of rubbing the liver with gauze to create adhesions between it and the peritoneum, because of the unnecessary injury to that organ.

General anesthesia is preferable as it allows more thorough inspection of the abdominal contents, and as the shock under present-day methods of administration is practically nil.

In conclusion, he states that he believes that omentopexy is a justifiable operation for cirrhosis of the liver; that the brilliant results of some of the operations would make it a rational procedure in the most desperate cases that may be complicated by cardiac, renal, or pulmonary disease.

The ideal technic under general anesthesia, consists of a median incision, below the umbilicus, suturing as much of the omentum to the abdominal wall as possible, drainage to be maintained at least one week.

G. P. G.

III.—THE OPERATIVE TREATMENT OF GASTRO-ENTEROPTOSIS.

Joseph Ransohoff, Cincinnati. *Boston Medical and Surgical Journal*, August, 1912.

Ransohoff believes that a great many of these cases are operable and in a lengthy article gives his reason for arriving at that conclusion. Where a great many men of large

experience and great authority in matters surgical hold out against operative interference, it requires conviction born of a series of successes to advocate the use of the knife, when other measures have failed. In extreme cases of this condition, which he terms "panoptosis," surgery offers but little, since this condition is congenital or easily recognized during the growing period of the child. The postural, combined with the mechanical treatment, if instituted early enough, must be of great benefit. Other cases in which the sagging of the abdominal or pelvic organs is associated with remote effects that hardly seem correlated. They are attributed for the main part to intestinal stasis. To this he also attributes the neurasthenic states that are so often associated with visceroptosis. While few have followed where Lane has led we are indebted to him for a clear, explicit pronouncement of the causes and dire results both local and general of fecal stasis. The variations of a fully developed adult visceroptosis are many, but he gives two conditions that he believes merit more attention than has been given them. The first is the insufficient fixation of the cecum and the ascending colon. The second is the relative high fixation of the splenic flexure of the colon with consequent sharp angulation at that point.

The fecal current is first arrested in the cecum after being rushed in a little more than two hours through many feet of small bowel, and it is here that stasis normally occurs. Without the proper support given by a normal fixation, "coccatony" as Fisher calls it is liable to ensue and with it all of the secondary local and general manifestations incident thereto. With delayed drainage the autotoxic symptoms become pronounced and finally neurasthenia is the outcome. As he aptly puts it, it is a far cry from mobile cecum to neurasthenia, but it is making itself heard. To illustrate this he cites a case. A woman came to him, a typical neurasthenic that had been treated for many ailments without any relief. Operation revealed a freely movable cecum that was partially obstructed at its upper part by an adhesion from this the cecum was enormously distended. The operation completely cured her of the pain, constipation, and neurasthenia.

He warns against the small incisions even in interval appendix cases for fear of overlooking the true cause of the patient's suffering. For the sagging transverse colon he uses as a routine the operation of colopexy as devised by Coffey. The operation to be effective, the suspension must be made, as far as possible, on both sides of the median incision. He divides the peritoneum, exposing the fascia, because it has been shown that peritoneal adhesions often stretch and some-

times disappear. The omentum is then fixed into these denuded areas by a continuous suture. The advantages of this operation is that it restores the natural, though always weak shelf-like arrangement of the transverse mesocolon, above which the stomach, so often prolapsed, is restored to place. No one operation is applicable to all the cases of ptosis of the colon. A careful study of a radiograph and then the actual conditions as seen through a large incision will determine the proper operative procedure.

Fixation operations of the cecum, transverse colon, or sigmoid, according to the indications, have in his experience sufficed and if performed early enough, will in his opinion, make unnecessary the decidedly more dangerous exclusion operations.

Gastroptosis is not rare as a primary condition. It is usually associated with a sagging of the colon, but it may exist alone as the only malposition present. Radiography is as important in this class of work as in any branch of medicine. By the X-ray not only is the position of the stomach shown, but what is more important its tone. From X-ray findings gastroptosis may be divided into two classes. The first in which the stomach retains its vertical position and the pylorus, although prolapsed, still occupies a low point. In the second class the stomach occupies a transverse position in which the greater curvature and fundus are greatly depressed, the pylorus remaining on a higher level. The functional disturbances are more pronounced in the latter class, because of the angulation that occurs at the gastroduodenal junction and because the chyme mass must be lifted uphill. For the operative relief of this condition he prefers an omentopexy or practically the same operation as described for coloptosis. He prefers this to the operation of Beyer, as he thinks the function of the gastrohepatic omentum as a suspensory ligament is doubtful, as it is employed in this operation.

In conclusion he summarizes his views on gastroenteroptosis as follows:

(1) Every case of visceral sagging should be studied individually, and should not be treated in a routine way, whether conservatively or by operation.

(2) If after removal of a normal appendix without relief do not class the patient as a hopeless neurotic. It is possible that some visceral displacement or adhesion has been overlooked, that is causing the pain.

(3) A small incision in the kind of work under consideration has signal disadvantages.

(4) In many seemingly hopeless cases of gastroenteroptosis with marked neurasthenic symptoms operation promises relief. If this

is the result of suggestion it is none the less valuable if the relief is permanent.

(5) Internal treatment, abdominal supports and postural treatment should be tried, operative interference should not be delayed lest the habitus nervosus becomes too deep-seated to be eradicated.

(6) No gastroptotic patient should be operated upon unless some functional disturbance can be demonstrated. To relieve this must be the aim of the operation.

(7) Given a visceroptosis in which we can elicit distinct functional incompetence or deviation, the existence of nervous phenomena does not militate against operation, but may be the chief reason for performing it.

G. P. G.

SAFETY IN THE OPERATIVE FIXATION OF INFECTED FRACTURES OF THE LONG BONES; Howard Lilienthal, (*Annals of Surgery*, July, 1912). Realizing that a secondary operation often follows plating an infected fracture after the method of Lane, Lilienthal has devised two methods of direct operative fixation, the apparatus used to remain in the tissues only until the plastic exudate would make it possible to maintain satisfactory position. The first method is accomplished by means of four gimlets, each being composed of a screw, a slender shaft and a square head. The latter is made to fit a key or brace. The gimlets are driven firmly into the fragments, two above and two below the fracture, the four forming a more or less straight line. The fracture is now reduced under direct inspection, and so retained by an assistant while two small steel rods are applied in such a way, along the line of gimlets and roughly parallel to the bone, that the rods and gimlets are in contact. If the gimlets happen to be in perfect alignment, the rods fit on either side of their shafts; otherwise, the rods are woven in and out among the gimlets. In either case they are kept near the gimlet heads away from the skin. In this position plaster bandages are wound about the rods and gimlets until the whole forms a rigid mass. The wound is not sutured, but packed from the bottom after thorough disinfection, and a dressing applied, with external splints. At the end of three weeks the gimlets will have become loosened and can be removed painlessly, and the wound, if found to be aseptic, closed with adhesive plaster.

Lilienthal's second method is mechanically more perfect, as it allows a plate to be screwed down upon the bone shaft. The plate is similar to Lane's except that at either end is a small projection, containing an eye. The under surface of this projection is grooved, so that when a wire is passed through the eye and the plate applied to the bone, the wire lying in the groove does not press upon the

periosteum. The plate is now screwed down upon the bone by means of the gimlets, whose shafts, as well as the wire from each end of the plate, project above the skin. At the end of two to four weeks, the gimlets are unscrewed of the plate removed by traction upon one wire or the other, as seems best. The advantage of being able to easily remove the plate impressed itself upon Lilienthal, when he learned of a case of re-fracture after successful plating, the break occurring not at the old site, but through one of the screw holes.—A. L. P.

CONSERVATIVE TREATMENT OF GIANT-CELL SARCOMA, WITH A STUDY OF BONE TRANSPLANTATION; Joseph C. Bloodgood, (*Annals of Surgery*, Aug., 1912). Bloodgood is firmly convinced that giant-cell sarcoma is not nearly so malignant as has been heretofore supposed. His own experience and his review of the literature led him to earnestly advise conservative operative measures. In addition to 26 personal cases, he has carefully studied as many more from the literature, and summarizes his results as follows:

1. Cases cured by curetting 11
2. Cases recurring after one curetting cured by a second curetting 1
3. Cases recurring after a curetting cured later by a resection. 3
4. Cases recurring after a curetting cured later by amputation 1
5. Cases which remained well after section 21
6. Cases which have recurred after resection but remained well after amputation 1
7. Cases subjected to primary amputation 14

He urges the use of the X-ray in all bone injuries, hoping thereby to detect the lesion so early that curettage will be sufficient.

He does not think that Coley is justified in including cases of giant-cell sarcoma among his cured cases as additional evidence of the efficacy of his serum. All of Bloodgood's 26 cases are well, some after ten years, and no treatment other than curettage, excision, or amputation was used.

The preponderance of giant-cell sarcoma of the lower end of the radius is noted, and Bloodgood regrets that his inexperience led him to amputate in four of his nine cases. Now he would advocate simple curettage, with transplantation of bone to fill the cavity. In such localities as the upper end of the fibula and in all cases where the bone capsule is perforated, he advocates resection. In all cases he disinfects the cavity with carbolic acid and alcohol.

He believes the term "sarcoma" should be dropped and "tumor" substituted, thus weaning the profession away from the faulty idea of the malignancy of giant-cell sarcoma.

He emphasizes his main points as follows:

1. Up to the present time we have no proof that the pure giant-cell sarcoma ever metastasizes. It is a question, therefore, whether it should be called a sarcoma.

2. Conservative treatment is justifiable. Curetting should in some localizations of the tumor, be the operation of choice.

3. It is justifiable to attempt curetting to preserve function, even when conditions suggest a great probability of recurrence.

4. Among 26 cases subjected to curetting there were five recurrences: one has remained well after a second curetting; three after resection, and one after amputation. I am confident that the number of successful cases of curetting will depend chiefly on the number of attempts.

5. Twenty-two cases were subjected to primary resection: one recurred and was cured by amputation.

6. As I found only five cases in the literature of giant-cell sarcoma subjected to primary amputation, and there are nine in my own list, one can feel pretty certain that many of these cases are not reported, except in statistical studies from large clinics.

7. After curetting or resection, the wound should be disinfected with pure carbolic acid followed by alcohol or chloride of zinc solution.

8. It is not necessary to perform the bone transplantation at the primary operation unless a single bone like the humerus or femur is divided in its continuity.

9. My experience teaches me that it is simpler, when possible, to get the bone for filling the defect by splitting the bone which has been resected.

10. In every case in which the X-ray shows a medullary shadow the urine should be examined for Bence-Jones bodies; the latter indicate the presence of a multitude myeloma, or metastatic carcinoma.

11. I would caution against the surgeon making a positive diagnosis of either a bone cyst or a giant-cell sarcoma. The more X-rays I see, the less confidence have I in my ability to make a differential diagnosis, except in the latter stages.

12. The positive diagnosis must be made at the exploratory incision. The bone cyst as a rule can be recognized by its blood-stained contents; the giant-cell sarcoma by its red, vascular tissue, which looks like granulation tissue. But the giant-cell tumor often has white areas of osteitis fibrosa often red giant-cell areas. The two are often mixed. One tissue, however, predominates. The less ex-

perienced surgeon should always aid himself with a frozen section. The giant-cell tumor occurring as a blood cyst may be encountered. The rare bone aneurism discussed in my previous report will be difficult to differentiate from the giant-cell tumor of the type described by Davis. Since my first report I have had one other observation in which the hemorrhagic tissue forming the wall of the blood cavity resembled closely a giant-cell-sarcoma, but the frozen section demonstrated the practical absence of giant-cells.—A. L. P.

THE LOUISVILLE MEETING.

"The Latch-String Hangs on the Outside."

The Jefferson County Medical Society extends a cordial invitation to every member of the Kentucky State Medical Association to attend the 1912 meeting to be held in Louisville October 29th, 30th, 31st, and assures them of a most hearty welcome.

The Society has secured the most beautiful and the most comfortable meeting place in the city of Louisville—right in the heart of the city—the First Christian Church (better known as Dr. Powell's Church), for the meetings, as well as the scientific and commercial exhibits.

The Committee on Arrangements, with the aid of its energetic sub-committees on finance, entertainment and hotel accommodations, has made the most elaborate preparations for the comfort and entertainment of its guests.

The members of the Jefferson County Medical Society have contributed very liberally to the fund for the entertainment of our guests, and their only desire is that the attendance may be a large and representative one.

The entire membership of the Jefferson County Medical Society is actively interested in the coming meeting, and every one of the two hundred and sixty members will constitute himself a Reception Committee.

COMMITTEES.

Arrangements.—Edward Speidel, Chairman; A. C. L. Perceful, C. H. Harris.

Finance.—E. L. Henderson, Chairman; Milton Board, D. Y. Keith, Guy P. Grigsby, E. F. Horine, J. B. Lukins, Jethra Hancock, J. A. O. Brennan, W. Bartlett Owen, Wm. A. Keller, C. G. Forsee, B. J. O'Connor, H. A. Davidson, C. T. Wolfe, Wm. Sanders.

Entertainment.—Louis Frank, Chairman; H. H. Grant, L. S. McMurtry, Henry Enos Tuley, Ap Morgan Vance, Harry J. Phillips, Jno. J. Moren, David C. Morton, Jno. G. Cecil, Dunning S. Wilson, Cuthbert Thompson, W. C. Dugan, J. Garland Sherrill, Wm. H. Wathen, W. Ed Grant, Irvin Abell, I. N. Bloom, Wm. Cheatham, S. G. Dabney, J. M. Ray, G. S. Haues, Bernard Asman, Chas. W. Hibbitt,

E. S. Allen, Virgil E. Simpson, Charles G. Lucas, J. B. Marvin, J. M. Mathews, Adolph O. Pfingst, Curran Pope, W. O. Roberts, B. F. Zimmerman.

Hotels and Information.—Henry Enos Tuley, A. C. L. Perceful.

Ladies' Entertainment.—Mrs. H. H. Grant, Chairman; Miss Marie Louise McMurtry, Mesdames. Henry Enos Tuley, Ap Morgan Vance, Harry J. Phillips, Jno. J. Moren, David C. Morton, Jno. G. Cecil, Dunning S. Wilson, Cuthbert Thompson, Louis Frank, W. C. Dugan, W. H. Wathen, W. Ed Grant, Irvin Abell, I. N. Bloom, S. G. Dabney, J. M. Ray, Bernard Asman, E. S. Allen, Charles G. Lucas, J. B. Marvin, J. M. Mathews, Adolph O. Pfingst, W. O. Roberts, B. F. Zimmerman, Edward Speidel.

Reception.—Every member of the Jefferson County Medical Society.

PROBLEMS AND DIFFICULTIES OF THE HEALTH OFFICER.*

By S. B. ROBINSON, Warsaw.

The health officer who is faithful in the discharge of his duty will have many problems to solve and many difficulties to overcome.

The remuneration is so small that the work he does is almost a labor of love, and there is so much to be done that, in a great many cases, he gives up doing anything but the most necessary requirements of quarantining the contagious diseases and making efforts to abate nuisances when they are complained of.

The health officer who does his duty of course will receive the approval of some and he will also meet with opposition from sources from which he would expect only cooperation and encouragement.

But the knowledge and satisfaction of having met the demands of duty will be some recompense for the time spent and all inconveniences experienced.

The great problem of how best to educate the people and get before them the great and vital questions that demand our attention now confronts us.

How are we to educate the people of this Commonwealth upon the great subject of preventable diseases to which we are so susceptible, and how are we to induce them to make a great and united effort to overcome these diseases?

This great responsibility rests upon the shoulders of the medical men and the educators of the people.

The prejudice against vaccination is giving way before the better education of the rising generation, though a number of the older in-

*Read before the school for Health Officers, Louisville July 8, 9, 10, 1912.

habitants and more superstitious are opposed to it, claiming they would much prefer to have smallpox as they have it now than be vaccinated.

We must educate the people upon the subject of tuberculosis, of typhoid fever, of diphtheria and other preventable diseases, all of which may be driven from our midst if proper hygienic and sanitary conditions can be brought about.

Thanks to the persistent efforts of the Secretary of the State Board of Health, there is now a well equipped laboratory and a competent bacteriologist in charge to whom we can submit any specimen and get a report upon it without any cost whatever. This will prove a great help to us in many ways, and a great aid in making a diagnosis of many difficult and obscure cases.

The problem of educating the teachers and parents upon the subjects of proper heating, lighting and ventilating of school houses, together with good drinking water should receive the attention of the thoughtful physician and health officer.

The problem of proper feeding, clothing, bathing and exercise for children should receive our attention.

If the county school superintendent and county health officer will work together and have these subjects discussed at school institutes and at school meetings in each precinct of the county bringing out the great benefit to be derived from adopting improved methods along all these lines, then we will begin to solve some of these problems.

If the health officer will discuss the subject of farm sanitation at the farmers' institutes he can do a great work in improving the health of the people.

The cities of this country have solved the problem of having a good and wholesome milk supply by placing "commissions" in charge of that important article of food and having a bacteriologist to see that the milk supply comes up to a certain standard, this has resulted in improved conditions of health in these cities and especially among the children.

Outside the cities we must accept the milk as it comes to us from the milk-man, trusting to him for its purity.

If the health officer and physicians of each county would take up this very important subject with the farmers, explaining to them the importance of furnishing milk only from absolutely healthy cows, and especially that they should be free from tuberculosis, that cows should have plenty of pure, fresh water to drink, good pasture, and other food, it would most certainly result in improved conditions of health.

It is claimed that every cow furnishing milk

for infants should be tuberculin tested, this is almost impossible in every community, but the condition of the cows should be closely guarded. None but the absolutely healthy should be allowed to milk.

No one nursing, or about the sick should be allowed to milk.

Milking should be done in a dust free room for dust contains a great number of bacteria.

The body of the cow must be clean and wiped with a damp rag before milking.

The bag and teats must be washed clean and dried before milking.

The bacteria found in manure and the dirt on the cow's body attack the fat and proteid of the milk producing rancidity of fat and many changes in proteids, sometimes poisonous products are produced by the action of bacteria on proteids.

The milker should have clean hands and the milk pails should be perfectly clean.

Milk should be immediately cooled and placed upon ice and kept at a temperature of 45 degrees or below to stop the development of bacteria.

With cows free of tuberculosis, and otherwise healthy, and the suggestions carried out as above indicated we ought to have milk that is perfectly safe for the baby.

Pasteurization destroys most of the bacteria in milk but it should be immediately cooled to prevent development of bacteria that would attack the proteid of the milk, and it is thought that the products of these bacteria are poisonous.

The number of bacteria in milk is an index to its freshness and precautions taken in milking and handling the product. A count of 100,000 per c.c. is not fit for infant feeding, but a count of 10,000 or less is desirable.

Bacteria in milk may be divided into two classes: the pathogenic and non-pathogenic. Pasteurization or heating the milk to 140 or 150 degrees F. for 30 minutes kills all pathogenic germs and from 98 to 99 per cent of other bacteria.

After Pasteurization there is less inhibition to bacterial growth than in raw milk.

If you have no thermometer to get the temperature, heating the milk until a scum forms and holding it at that temperature for the time will be all sufficient.

Sterilization is boiling the milk for about 20 minutes, this destroys all bacteria and their spores, but we also destroy the power of the milk to inhibit their growth, and any contamination will be followed by marked increase of the number of bacteria in a few hours.

The chemical changes in sterilization of milk are very marked, but when it is only Pasteurized the changes are unimportant.

It is thought that fresh milk has some 

hibitive action on bacteria for after boiling bacteria growth is much more rapid than before.

It is our duty as physicians to bring before the people again and again the fact that consumption is a communicable disease through the sputa.

That every particle of this should be collected in spit cups or on paper and promptly burned.

They should know that open air, sunlight and abundance of food constitute mainly the treatment.

The typhoid fever problem should be handled by the medical men at public meetings and the infection by water, ice and flies fully explained.

The problem of dealing with the fly and mosquito should be brought prominently before the people.

It is claimed by a health officer of Washington, D. C., that from one female fly, in a single season, about eight billion flies may descend.

The housefly is now regarded as one of the most deadly enemies man has to contend with, he carries typhoid fever, tuberculosis, intestinal diseases, spinal meningitis and infantile paralysis, leaving the germs wherever he lights.

The mosquito problem should have our attention and the people taught that these pests carry malaria, yellow fever and filariasis.

It is only the female imago that sucks human blood and she is only active at night.

It is only in warm weather that mosquitoes appear to have any part in the transmission of disease.

Malaria rarely develops below 59 degrees F. and is completely checked at 32 degrees, at which temperature mosquitoes are very sluggish and do not bite.

In this country we have nine genera of mosquitoes represented by about twenty-four species, the larger number belong to the genus *Culex* and are quite harmless.

We have three of the eight or more species of malaria bearing anopheles, and the *Stegomyia* calopus, the carrier of yellow fever.

The *Stegomyia* is found in various southern states and does not bite at a temperature of 62 degrees F.

This will account for the decline in yellow fever as cool weather comes on.

Stagnant pools should be drained and kerosined to abate the breeding places of the mosquito; weeds which furnish hiding places for these pests should be cut.

School hygiene is one of our most important problems.

In the country districts medical inspection can not be carried out as faithfully as in the

city, but the teachers should be instructed in hygiene, and should report any appearance of ill health immediately.

They should report any contagious disease that may come into their school district.

Defects of eye, ear, nose, throat, etc., should be looked after and corrected.

The school house itself should be a model of ventilation, lighting and sanitation.

Every school should have a play-ground for the boys and also one for the girls; or if only one can be provided they should use it alternately.

The problem of educating the people upon the great subject of hygiene which is light, air, water, food, rest, exercise, etc., should have our attention.

The subject of preventive medicine should be brought before the people, especially of infectious diseases.

The germ origin of many diseases should be preached to the people, also the part played by water, impure food, insects, etc., as carriers of disease to man.

In order my friends, that the people may have confidence in all of these teachings, and in order that we may have the best influence for good in the community in which we live, we must practice what we preach and live up to them ourselves.

THE FORUM

To the Editor:

Prof. H. Strauss, of the University of Berlin, will give a lecture, in German, at the New York Post-Graduate Medical School and Hospital, Twentieth Street and Second Avenue, on "Gastric Secretion from the Therapeutic Point of View," on Monday, October 14th at 4 p. m., and at the same hour on Tuesday, October 15th, a lecture on "The Methods and Purpose of Dechlorination in Nephritis."

Prof. C. Von Noorden, of the University of Vienna, will give a series of lectures, in English, at the New York Post-Graduate Medical School and Hospital, on "New Aspects of the Pathology and Treatment of Diabetes," and on "Diagnosis and Treatment of Nephritis," beginning on Tuesday, October 29th, at 4 p. m., and continuing for four consecutive days, at the same hour.

Cards of admission upon application.

EDITORIAL

THE R. M. ROSE COMPANY.

A recent letter from the R. M. Rose Company to the Editor of the JOURNAL, proposing to give him a gallon of whisky for every ten they are shipping to inebriates in this neighborhood, in his name, is answered in this public way through the columns of the JOURNAL so that the profession of the State may know about this disgraceful offer. The State Medical Association will be glad to have information as to any doctor who has accepted the proposition set forth in a circular letter that was evidently sent out to physicians all over the State, as some fifty of them have already been received in the office. It will be a matter of regret to know that any man has so far forgotten the obligation to his profession and his State as to assist in this plain violation of the law, but if anyone has done it, we will take a great deal of pleasure in preferring charges against him so that he will not be in a position to continue to do so. The JOURNAL has nothing to do with the legitimate sale of whisky, but with a dishonorable and disgraceful proposition like this, we have an immediate and direct interest.

SCIENTIFIC EDITORIALS.

NASAL REFLEX NEUROSES.

The hay fever period has again come and gone and nothing new in a curative or palliative way has been offered the unfortunate stay-at-homes, afflicted with this disease. From time to time new therapeutic measures have been suggested for the relief of hay fever, but each year the multitude of sufferers from this nasal neurosis find that re-

lief can be obtained only by seeking of the northern climate. In this, as well as in other nasal reflex neuroses a certain percentage of cases can be cured or at least relieved by intra-nasal treatment between the periods of activity, a fact now generally recognized but to which we wish to call attention.

The nasal neuroses have been divided by Jurasz into three classes:

(1) Those in which the sensory origin is in the nose and the effect produced is outside of this organ—as in asthma, chorea, etc.

(2) Those in which the sensory impulses arises in the nose and the end result is in the nose—as in hay fever, and,

(3) Those in which the afferent impulse arises outside of the nose and the end result is in the nose—as in the congestion and hypersensitiveness of the nasal mucous membrane following sexual excitement.

It is now a conceded fact that all of these reflex conditions are dependent primarily upon a peculiar neurotic predisposition of the individual, but that the local (nasal) and the exciting causes are important factors in the production of the reflex act.

There was a time following the publications of Voltolini, Hock, and others, pointing out the etiological relations between intra-nasal troubles and reflex neuroses, that rhinologists in their enthusiasm over the curative possibilities of nasal treatment in these cases almost overlooked the constitutional predisposition. Later through the experimental study of Flies, Kuttner and others, it was demonstrated that hay-fever, asthma and kindred diseases, although dependent principally upon the general nervous condition of the patient, were in a great measure due to pathological conditions of the nasal mucous membrane. For a time it was believed that there were certain circumscribed areas in the nose which alone gave origin to the affected im-

pulse of the reflex act, but it is now known that the sensory impulse can arise from any part of the mucous membrane, whether supplied by the olfactory or the trifacial nerve.

Killian has demonstrated experimentally that the spine of the septum on each side and the posterior portion of the inferior turbinate bone are the most susceptible portions of the nose.

Of the nasal conditions which make the mucous membrane susceptible hypertrophy of the turbinate bones is perhaps the most common. The enlargement of the bone itself or hypertrophy of its mucous membrane brings it in contact with the septum and an increased irritability of the afferent nerves results. Irregularities of the septum of all kinds such as spurs, deflections, fractures, etc., are often brought in contact with the turbinates with a similar result.

While we have always recognized in nasal polypi one of the frequent causes of reflex troubles, it has only been in the last few years that disease of the accessory nasal sinuses, especially the ethmoid cells, have been recognized as etiological factors in these conditions. Adhesions of adjacent structures in the nose such as the turbinate bones with the septum, resulting from injuries, operations or ulcers are also frequently the cause of reflex trouble. With the irritability of the sensory nerves increased by the local pathological conditions, they become susceptible to such irritants as pollen of plants, powders of various kinds, odorous gases, etc. In the beginning of these troubles when the mucous membrane still approaches the normal, it takes quite a strong irritant to start the reflex paroxysm, but after repeated attacks the mucous membrane becomes more susceptible and responds to a milder stimulus. This is frequently noticed in asthma, and hay fever, where, after several years recurrence of the trouble, the nervous system has not carried out its normal functions for so long that it seems no longer capable of doing so, and in some cases, even though the nasal cause of the disease be removed, the trouble persists.

The most frequent reflex neuroses dependent upon a nasal origin are, asthma, epilepsy, chorea, and migraine. Cases of reflex angina pectoris and Basedow's disease are also on record.

A very interesting case illustrating the etiological relation between the nose and asthma, was recently observed by the writer in a young lady of 30 years, apparently in splendid health, who has been having typical attacks of asthma at irregular intervals for over a year. This patient had rather large tonsils, with many of the crypts filled with cheesy concretions, and had been advised by a competent rhinologist to have them removed, be-

lieving that they were responsible for the attacks of asthma. Casual examination of this patient's nasal passages led to the conclusion that they were normal, but a more careful examination after shrinking the mucous membrane with adrenalin-cocaine solution revealed a small polyp far back on the edge of the middle turbinate, and in contact with the septum. Removal of this polyp has given the patient perfect relief of her asthma. It is now six months since the operation.

Cases of chorea whose origin could be traced to pathological conditions in the nasal passages, and in which cure was brought about by nasal treatment are not uncommon. The most pronounced case of this kind which has come under the observation of the writer, occurred in a young man of 19 years, who had suffered with choreic twitching of the muscles of his face, neck and shoulders for two years. The trouble began several months after an injury to his nose during a foot ball game. This boy presented an angular deformity of his cartilagenous septum, almost completely blocking the right nasal passage. Eight months ago a sub-mucous resection of the septum was done giving him free breathing space. There was a gradual improvement until to-day he has about stopped all of his nervous movements. Prior to this operation the writer had removed a small adenoid and corrected his errors of refraction with lenses without benefit.

Reflex epilepsy of nasal origin was at one time believed to occur with greater frequency than it now is, many of these cases now being recognized as hysterical in origin. While the writer has had no personal experience with epilepsy originating in nasal conditions many authentic cases of the kind are on record, the epileptiform paroxysms occurring coincidentally with intra-nasal changes and cure following correction of the nasal conditions. It seems that the differentiation between epilepsy and convulsive hysteria is very difficult. Even the aura is not a positive sign as Charcot and others have shown that it is present at times also in hysterical cases. In epilepsy and in convulsive hysteria the nasal mucous membrane has similar sensitive areas whose stimulation may bring about the convulsive attack. Some authors have discredited the many wonderful cures of epilepsy by means of intra-nasal surgery, believing that many of them were of a hysterical nature and the cure the result of suggestion rather than the real result of the operation.

Nasal disorders have frequently been known to influence the circulatory system. Kassel reported a case in which contact with the nasal septum at the spine caused palpitation of the heart, and the palpitation entirely ceased after removal of the spine. Kratschner

demonstrated that slowing of the pulse frequently resulted when the nasal mucous membrane was stimulated, and Knobloch and Roder found in animals that stimulation of the nasal mucous membrane opposite the posterior extremity of the inferior turbinate bone brought about various forms of arrhythmia. The causes of Basedow's disease reported cured by intra-nasal surgery by Moritz Schmitt, and Hopman were evidently not true cases of this disease, but reflex changes in the vaso motor system. The theory is that the trigeminus stimulated in the nose sends its impulses to the sympathetic ganglia from where the vaso-motor impulses are sent out and the symptoms of Basedow's disease produced.

In late years the rather remarkable fact has been demonstrated that the nasal mucous membrane and the genital organs stand in direct relationship. Flies, Knobloch, and others have demonstrated erectile tissue at the spine of the nasal septum, while Flies reported a case of dysmenorrhoea in which the pain was stopped by application of cocaine to the nasal spine.

Whether hay fever, should, strictly speaking, be classed with the nasal reflex neuroses has not been decided. The morbid condition in the nose is one of hyperemia and edema depending upon vaso-motor disturbances, which most likely are the result of reflex stimulation arising in the nose. Phillips in his recent text book says, "The disease is probably a combination of a moderately severe neuroses, with local morbid changes, which give rise to the local irritation of the nerve endings of the sensitive branches of the sphenopalatine ganglia, upon which, at favorable seasons of the year, the pollen of certain plants and the emanations from certain animals, lodge and give rise to phenomena characteristic of hyperesthetic rhinitis."

Although many times in severe cases of hay fever we find no abnormalities in the nose except the puffy mucous membrane, we know that many of them are brought about by nasal conditions such as we have mentioned.

The treatment of nasal reflex neuroses even though they are due largely to the neurotic predisposition of the patient offers the most chances for relief through intra-nasal surgery. Surgery of the nose has made such progress in the last years that the possibility for cure has increased. It has not been many years since, that nasal polypi were treated as such by removing them as close to their origin as possible. While this in many instances has relieved the reflex troubles we know now that polypoid growths probably with few exceptions spring from the nasal accessory sinuses, and that reflex troubles are at times not cured until the primary (sinus) trouble is cured.

It has also only been in recent years that we are able by means of the sub-mucous resection of the nasal septum to obtain free nasal passage, and thereby relieve points of contact which was not possible with the old crude method of rebreaking and splinting the septum (Ash operation).

Cases without deformities or points of contact or adhesions are sometimes relieved by the application to the sensitive points of Kilham of trichloroacetic or chromic acid. As points of contact in the nose are subject to change in the amount of swelling of the mucous membrane, these cases should be given as free a breathing space as possible. Polypi should be removed, deflections corrected, adhesions separated and large turbinates wholly or partially resected. While most of the cases which are cured by intra-nasal surgery are real cures due to the correction in the nose, the writer is convinced that in a certain percentage of cases the cure is brought about by the psychic effect of the operation.

It goes without saying that general treatment should be given these patients and the irritant causes avoided as much as possible.

ADOLPH O. PFINGST.

THE NINTH INTERNATIONAL OTOLOGICAL CONGRESS.

The Ninth International Otological Congress met at Boston, August 12th-17th, about three hundred and fifty members being registered.

It was the first meeting that had been held in America since the organization of the Congress at New York City, in 1876, and was in many particulars a notable gathering.

The sessions of the Congress were held at the Harvard Medical School, which was a particularly happy choice.

These buildings, probably the most magnificent in the world used for the teaching of medicine, standing out with all the stateliness, grandeur and beauty of a Greek temple, are the very apotheosis of all that is greatest and best in medicine. It should be a matter of pride to all Americans that, notwithstanding our deficiencies in medical education in the past, we were able to offer an International Congress, for its sessions, a place dedicated to the teaching of medicine not to be surpassed in the whole world.

EXHIBITS.

There were no commercial exhibits. Of the scientific exhibits, those of most interest were the extensive microscopical preparations of the internal ear, both in health and disease, many of these being particularly clear and easy to understand. (This can be readily ap-

preciated by one who has made his first essay in this work).

The other exhibit that deserves special mention was a series of X-ray plates, showing the diseased and healthy mastoid process. This method is now firmly established as a definite diagnostic agent, especially in doubtful cases.

SESSIONS.

The conduct of the sessions of the Congress was almost military in its discipline. Every essayist was held strictly to his allotted time. One had to indicate on cards sent to the Chairman his desire to take part in a discussion. No one who had not sent in his card was recognized. Discussion was mostly limited to three minutes, but the remarkable part of this was that the speaker often left part of his length of time unused.

At a meeting where all the papers were good, it would be impossible to pick out a particular few for mention.

To one who followed the sessions closely, the following points stood out in bold relief:

The value of autogenous vaccines in certain types of ear infections.

The value of blood cultures for the purpose of diagnosing sinus thrombosis or meningitis.

That consistent efforts are now being made to solve the meningitis problem; to increase our knowledge of its diagnosis, its classification and treatment.

The greatest interest and enthusiasm was shown to all problems dealing with the internal ear, especially the labyrinth, and enough has already been brought out to show that the otologist will soon be the complete master in that hitherto unknown region.

Finally, there came the consideration of the deaf child; the prevention of deafness; home treatment and schools for the deaf.

Probably the most dramatic session of the Congress was precipitated by a paper by Mr. Heath, of London, on "The Prevention of Deafness and Mortality Due to Aural Suppuration." The discussion of the paper waxed warm and even descended to personalities. Our English confreres, almost to a unit, condemned Mr. Heath and his work, and many of the Continental members took the same stand. Be it said for Mr. Heath that, the harder they hit, the more he seemed to enjoy it, and when it came time to close the discussion he took up his opponents, one by one, and disposed of them in full. He showed himself a master of debate as well as a great ear surgeon.

America, with but two exceptions, offered no open protest to Mr. Heath's work, and the surgeons of Boston supplied him with abundant clinical material to demonstrate what he could do. About that, more later.

This discussion, as well as many private

opinions the writer heard, discloses a state of unrest about the mastoid operation that might be disconcerting if it did not give promise of better things.

Such a state of affairs can mean but two things. Either there are several methods, equally good, of accomplishing the desired results; or, that dissatisfaction with the older methods has caused some to seek better results by newer procedures.

Let us hope that the very free discussion of this question will bring us to an unanimity of opinion that will indicate that we have reached bed-rock.

CLINICS.

Mr. Heath was in Boston in advance of the Congress and operated both before and during its sessions at the Massachusetts Eye and Ear Infirmary. He had in all about twelve cases, mostly acute, and his work excited general interest.

His operation must be seen to be understood. His primary incision hugs the posterior attachment of the auricle, which he dissects forward, hugging the cartilage till the cartilaginous canal is reached. This is separated and the auricle then drawn forward. It will be seen that the part drawn forward is only the cartilage and is thus ready for his plastic. Incisions backwards, through the soft parts above and below, with retraction, give the required bony exposure. He enters the antrum from in front, as in the Stacke operation, and cleans out the cells, but not entering the tip unless special indications exist. He cuts down the bony wall to the annulus as he proceeds. He then reams out the aditus with a special instrument and blows air through it out of the perforation in the tympanum. He is then ready for his plastic. He enters the knife at the superior portion of the cartilaginous canal and cuts downward and forward into the concha. He then cuts free the upper end of the flap by an incision inward in the superior wall. The flap is thus turned downward and backward, and sutured to the soft parts behind. He also enlarges the external canal by a cut outward in the concha, at the level of the top of the canal. When the flap is in position, a good view of the antrum and drum is obtained. He places two pledgets of cotton in the ear, one at the opening in the drum, one over the aditus, and sometimes one deep in the antrum. The posterior wound is closed and the after-treatment carried out through a large, fenestrated, rubber tube placed in the external meatus. The usual external dressing is applied.

The after-treatment is very simple, dressing being done through the external canal; the tube removed and cleaned and the exere-

tion wiped out with cotton pledgets. He has an antiseptic solution made, I believe, by saturating water with iodoform and boric acid. This solution, on cotton pledgets, is put into the wound at the aditus and over the tympanum, after removal of those placed in at the operation.

He insists, moreover, at each dressing, that air be forced through the Eustachian tube, out through the opening in the drum, and through the aditus. He has a special canula to keep the last pathway free from debris, and he believes that the stopping up of this passageway is the primary cause of mastoiditis.

I had also the good fortune to see Mr. Balance apply a large primary graft following a radical operation at the same institution. After a carefully executed radical, he cuts a large thin graft from the inner surface of the thigh. This he smooths out on a large spatula and, after carefully wiping out the wound, transfers it into the cavity. In order to get close apposition in all directions; he inserts a glass pipette under the graft, sucking out air and secretions while he presses the graft in place from above. He uses small pledgets of cotton covered with ——— to hold the graft in place, and closes the posterior wound. He sews the flap of his plastic backward, making an ample external meatus, and carries on the after-treatment through this opening.

Professor Neumann did a labyrinth operation at the Boston City Hospital, on a patient who had a previous radical operation performed. He enters the labyrinth from behind, working just anterior to the sinus, and enters the semi-circular canals from this position. He then opens the cochlea by chiseling away the promontory.

Mr. Richard Lake, of London, demonstrated an ingenious larynith operation on the cadaver. The incision and exposure he gets is different from any other operation. He places his knife in the meatus, edge up, and cuts from the drum outward. The incision then swings forward to the beginning of the helix and follows the attachment of the auricle till about half-way down; then it turns out over the mastoid. He then literally dissects the auricle and cartilaginous canal from all its attachments except below, so that it can be retracted down on the neck. He then enters the antrum from in front with a hand gouge, cutting down the posterior bony wall through the annulus as he proceeds. He enters the labyrinth through the external semi-circular canal, gradually uncovering the others, and after communication is established between these, he breaks open the cochlea by chiseling away the promontory. He then brings the ear back into place without drainage, flaps or packing. He makes no ef-

fort to keep the external canal patent, since the ear is dead following the operation. He uses a number of special instruments for his operation.

As a fitting climax to the sessions, the last afternoon was devoted to the methods of teaching the deaf, and the importance and necessity of having properly trained teachers in every community who can carry on this work. The importance of early training by the mother was emphasized, and that the doctor should instruct the mother as to her duties during this period.

All agree that lip-reading should be taught exclusively, if possible; that in all cases it is the method of choice, and that the manual method should occupy a subordinate place, or be used in cases where eye-sight is also wanting.

To demonstrate the possibilities of teaching the deaf, Professor Wright, of New York, exhibited several of his pupils who spoke to the Congress, and could understand perfectly everything that was said, though they had been entirely deaf since infancy, thus illustrating the possibilities of lip-reading.

He also had with him Miss Helen Kellar, who addressed the Congress and plead with the profession not to lose themselves in the glamour of surgical achievement, but to give a portion of their attention to the education of, and the betterment of the condition of the deaf child.

The profession of our own State should give heed to the voice of this wonderful girl, and see to it that we have some one to teach these unfortunates.

With this demonstration, the Congress closed, to meet again in Berlin, in 1915.

GAYLORD C. HALL.

NEUROLOGICAL CLINICS.

The writer has just returned from a two weeks' attendance at the International Clinics of Neurology and Psychiatry, held at Fordham University in the city of New York. Too much praise cannot be given to this enterprising university, the faculty of which has undertaken to initiate a special extension course, so as to bring together the foremost men of Europe and America. This clinico-lecture course surpassed anything that it has ever been the pleasure of the writer to attend. Each line of neurology was well represented and the work done masterly in every particular. To attempt to in any wise detail the remarkable work of the Englishmen and Germans would be foreign to this editorial, but that neurology and psychiatry will be benefited, and many men in America stimulated to greater endeavor and to more research is unquestioned. The writer's personal opinion

is that Drs. Henry Head and Gordon Holmes undoubtedly carried off the palm, so far as the work in neurology was concerned. Both of these gentlemen are genial, sociable and clinical teachers of unusual ability. It was their plan to first outline the anatomy of the central nervous system, sensory and motor, indicate the symptoms that would follow certain lesions, and the pathology that likely would cause them, and the symptoms having localizable value. Having mapped out the anatomico-pathological ground work, they then introduced patients upon whom they were able to demonstrate the various lesions that had been shown in the theoretical and didactic portion of their lectures, a living verification of their investigations, and this was the same method followed by Russell in his course upon Tabes, a line of work to which he has given much time and attention.

Psychiatry was well represented by that past grand master investigator, Dr. C. J. Jung, of the University of Zurich, who lectured upon the psychology that is now generally termed Freudian, and which has largely been substantiated and supported by Jung in his scientific investigations by means of the association test and psychoanalysis. Representing the other side of the question was Dr. Alwyn Knauer of Munich, one of the principal workers in Kraepelin's Clinic. His lectures upon paranoia and paranoid conditions presented many new and interesting facts from the position that Kraepelin assumes. The normal and pathological microscopical anatomy of central nervous system was ably and well covered and extensively illustrated by colored lantern slides by Dr. Nicholas Achucarro, of Madrid.

It is with pride, that we Americans can feel that we were well represented. There were no better demonstrations, no cleverer teachers, and no more sincere workers than Messrs. Jelliffe, White, Goddard and May, to say nothing of the faculty of Fordham University, headed by that genial and pleasant son of old Ireland, Dr. Walsh. American neurologists and psychiatrists owe to Fordham University a debt of gratitude, and it is to be hoped that the faculty and trustees will repeat these extension courses and continue to bring to our doors the best talent of the old world, not alone in neurology and psychiatry, but other branches of the healing art in order that we Americans may profit by their teachings and presence. They have undoubtedly stimulated us to better endeavor to harder work. A pleasant feature of the course, was the reception given by Dr. and Mrs. Jelliffe.

CURRAN POPE.

PRESIDENT'S ADDRESS*

DAVID O. HANCOCK, Henderson.

No nobler virtue warms the knightly heart than that of gratitude. No rose blooms on the wall of life without the application of a human hand near the root of it. Work,—work only can bring to us the semblance of dreams come true. There are exquisite moments in life, let people say what they will of the disappointments and vanity of the world, when hope is realized, desire fulfilled; but it is just for a moment, no more, just a fore-taste of the joys that shall be hereafter, when every moment of the long years of eternity will be still more full and perfect,—when we shall wake up and be satisfied.

Those exquisite moments are mine to-day. It is your work that brings to me the "semblance of dreams come true." By your leave I am the recipient of the most distinguished honor which you can bestow—President of Kentucky State Medical Association. I would be untrue to every instinct of my nature did I not attempt an expression of admiration for the hands that digged about the roots of the vine that has blossomed so gloriously into my life. The attempt brings to me Helburn's stanza to mother:

I have praised many loved ones in my song,
And yet I stand
Before her shrine, to whom all things belong,
With empty hands.
Perhaps the ripening future holds a time
For things unsaid;
Not now; men do not celebrate in rhyme
Their daily bread.

He who has made acquisition of a judicious and sympathizing friend, may be said to have doubled his mental resources. This being true I turn again to the duties of the office with assurance that my resources are many times increased.

Nature might have said of Brutus.—This was a man! So of 1912, this is a year. One of extraordinary development. It is good to live and have part in such a year. Notwithstanding deplorable accidents man is flying farther and higher and faster than ever before. This is true in every department of life. We read of embezzlements, scandals, divorces, etc. But we remember that 10,000 bank cashiers have not defaulted; that 100,000 preachers are faithful and virtuous; that 20,000,000 married couples have not sought divorces; that 10,000,000 of laborers have kept sober all the year; that 90,000,000 of our citizens have not suicided; and that millions and millions of people have made railroad trips without

*Delivered before the Kentucky State Medical Association, held at Louisville, October 28-31, 1912.

accident. And that the benefactions of the year are 150,000,000; and that our wealth is estimated on Wall Street at billions and billions.

Our people have learned and are learning that whatever their ideals, ambitions, and impulses, disease is the iconoclast which shatters and destroys. Its maw is filled with the bodies of millions who should to-day be enjoying the pleasures of life and contributing to the sum of human happiness. And having learned they are calling: Come and help us. Medical research unhampered, and encouraged by State, will soon have laid the foundation for a condition of life which can not be even imagined to-day. The young adult of the present will then have just entered his childhood; and the old man his prime. The economical and social conditions of a relatively disease-free existence would read like a fairy-tale. Medical science is doing its duty toward hastening this millenium. There will be no relaxation of energy in this humanitarian undertaking to which the medical profession is committed. Our science is continually placing new responsibility upon society and society must undertake an adaptation under the pressure of its postulate. Every discovery effects society in proportion to its utility. Society as a result must shift its attitude and change its conduct. These are beneficent adaptations and proceed to a higher plane. Disease is to be viewed as a sociological problem or accident, to be solved or repaired for the high and important reason, namely, to restore the patient to health, that society might suffer as little disturbance as possible. Ignorance in the body-politic, and violations of the civil and religious code should be viewed in the same light by, the educator, the lawyer, and the minister. Whatever interferes with the uplift of humanity is the arch-enemy of the race. All professions should unite in a common attack upon a common enemy. No single factor makes greater contribution to human happiness than health. The whole tendency of medicine is to conserve it, for the public good. The lives of Jenner, Koch, Reed, Carroll, Flexner, and others bear evidence.

Supervision of every condition which bears on public health and the enlightenment of the people on matters of the cause and prevention of disease, is a fundamental function of government; a bonnden duty which it should perform. (Gladstone). Government has wisely provided, Departments of Justice, Agriculture, Education, etc. Advanced civilization holds it as important to conserve the health of men, women and children, as it is to prevent violations of the civil law or to punish culprits.

The education of children is no more a duty of State than to protect them from diseases

which incapacitate them for the highest citizenship. To cure tick in cattle, cholera in hogs, and glanders in horses, are not more proper functions of government than the prevention of tuberculosis in the parents of our sons and daughters. Only the rankest strabismic statesmanship would deny the right of the State to provide for a system of State medicine to be administered in the interest of the health of all the people, without prejudice against any sect or combination of lawful interests. Usefulness depends on the frankness and success with which we attack and solve problems affecting the life, health and happiness of the people. The supreme duty of the Nation is the conservation of human resources through on intelligent measure of social and industrial justice.

We shall not destroy our means of earning a living by engaging whole-heartedly in this humanitarian work. On the contrary we shall add materially thereto. The practice of medicine is in a transitional stage. Certain sources of our revenue are being cut off by modern thought. No one hails this with more delight than the honest physician. We are glad to discard all forms of mental therapy, which are devoid of a rational basis, and concentrate our energies on more worthy fields. The general law of society is, Those who serve are supported. Every one should know how to protect and prolong his life, and how to safeguard his happiness. A better public intelligence will mean more medical work. Our best sources of income is from those diseases which least disturb the community, the family and the individual. A completely disabling disease of several months makes the average patient a source of loss to the physician. Patients past 30 years are the most profitable. Our revenues are increased by a decrease of infant mortality.

One out of every twelve babies die of birth accident, and there should be no birth accidents. One out of every four babies die of intestinal diseases. These deaths are unnecessary. Proper supervision in life prevents heart and kidney diseases. There is a stage in every case of consumption in which a cure may be had in three months. Not one-tenth of tonsils are removed, which should be removed. Adenoids are giving untold trouble. Thousands of people are working at low efficiency by reason of poor sight. There are not enough surgeons to do all the work demanded by a consideration of the greatest efficiency, comfort and happiness. The field is indeed white unto harvest.

Another source of useful work is that created by the new order of things. Health departments are community agencies. The people look to them for health conservation. They should find physicians in charge, train-

ed and equal to all requirements. The same is true of tuberculosis societies, and every other society which works for the protection of the lives and health of the community. The future of the profession depends on keeping matters so that when the public thinks of these things they automatically think of physicians, and not of sociologist and sanitary engineers. In this department of our legitimate work there is lucrative employment for all the capable doctors that can be produced in the next quarter of a century. This all means re-adjustment of medical work. Those who can not give high grade work will be eliminated. Those who serve are supported. The remedy is,—take active part in medical society work; on medical boards; read good journals; and take other advantages which qualify them for real service. If they will not do this, then they must look elsewhere for employment.

If we would have anything of benefit we must earn it; and earning it become, shrewd, inventive, ingenious, active enterprising. Having done this it is not sufficient that we experience an exhilaration which discharges itself in good humor on others. The laborer is worthy of his hire, applies to doctors. We should no longer give 25% to 50% of our earnings to charity. Tithing was the tenth. More is a hardship on us; and pauperizes the recipient. Eighty per cent of physicians collect less than 75% on their accounts. More than 500 doctors in Kentucky are serving on boards of health without pay. Three thousand six hundred doctors in our State are making vital statistic reports at less than 1-3 that paid court clerks for less work. More than 600 registrars are reporting births and deaths at 25 cents. County health officers get \$100 to \$300, where county judges and attorneys are paid \$1000 to \$3000. Why this *flagrant discrimination against doctors and the health of the people?* It is high time that we throw off these burdens and teach the people to pay for what they get. Laboratories, research, and prevention will soon constitute a large part of our work. Compensation for these services is an essential to their existence. We must educate the people along these lines for their own good as well as ours. To this end there must be an ever-increasing closer federation of our profession within itself, and with other professions and the public.

Medical organization suggests one name to every doctor in Kentucky. His magic wand has been felt in every state. An investigation of his more than a quarter of a century of public service has awakened an appreciation of this man. I here interpolate the gratitude of the medical profession of Kentucky to him. The organization of our State Associa-

tion is one of the best. There is nothing, however, but must be improved or changed as time and conditions change. The backward look is instructive. All that we have we gathered up on the paths that lie behind us. The spirits attitude of reverence for the treasures of the past is proof that the hall-mark of heaven is stamped on human nature. Gratitude is heavenly; justice is divine. The soul uncovering its head before the richness it has appropriated and assimilated, is a soul on the eternal ascent. Such a picture should have a place where hangs the masterpieces, on the walls of human experience. These possessions once rich and radiant were the essence and symbols of completeness yesterday. They are limitations to-day. In the fuller light of the broadening present they seem meager and mean. We must change and continue to change.

The years' experience of men engaged in association work has a message for us. Gov. Woodrow Wilson said to the American Medical Association: "It should be our object to unite ourselves with one unified interest, moving forward to the common goal of general service. I therefore ask you in your modern occupation to harmonize the various parts of our whole life to one another; so that heat, hostility, and friction may be taken out, and all the sweet and wholesome processes of life may be restored. President John B. Murphy said in his address, "It is important in every great organization, that rotation in positions of power and trust take place, otherwise in time, regardless of efforts that may be made to the contrary, personal interests, or idiosyncrasies, likes and dislikes, will dominate its management, which will of necessity be to the detriment of the whole. This rotation should be automatic in order that it may be entirely impersonal and democratic."

Again Dr. Murphy advised, "The house of delegates should and must remain in absolute control of every interest of this Association, and see to it that no individual, or combination of individuals, or council or board of trustees, can thwart its will, divert its force, ignore its instructions, or assume ownership of it. It has been and must remain the sovereign power."

Business meetings should be held uniformly in December as provided in the Constitution. The list of delegates should be published in the JOURNAL early in the year. The Secretary can not do this while elections are deferred.

Uniformity of program for county societies is feasible. I have prepared an outline for such a program and submitted it to the House of Delegates.

The program of the general meeting of 1912 has been prepared in sections, by sub-

committees as indicated in the published program in the September JOURNAL. We hope that this added council has given strength to the work. The Committee on Scientific Work compiled and published it.

A few exerecisees remain on the body of the Association. Old line insurance examinations are being made for less than \$5.00, and by members of the State Association. Especially are young men being tempted by a few pieces of silver.

Division of fees continue to disturb. When to a just fee there is added a sum which being turned over to the physician in charge, converts him into the financial agent of the surgeon, it becomes disgraceful robbery. Thou shalt not steal, applies to physicians and surgeons.

The abuses of contract practice; the degradation of underbidding for practice; direct and indirect advertising for work; and other matters might be discussed. All are but parasitic growths on our profession. They can not be ignored; but should not be magnified. "Every cure of the world's woes, whether concocted by philanthropic, political, socialistic, or parliamentary, combinations, that seeks to change the hearts and lives of men without the recognition and intervention of God, is a mockery, a delusion, and a snare." (Gen. Wm. Booth). We may not undertake a camp-meeting to convert these offenders. But we should make more distinct the line of demarcation between these men, and doctors of courtesy, fairness and common honesty. We should enhance the value of honorable membership in our county and State associations and place a ban on those who make themselves dishonorable. A discriminating public will do the rest.

There are 2200 members of the State Association. Fourteen hundred doctors in Kentucky are not members. The need of closer organization is apparent. Forty per cent of non-members is too great. I believe that the plan for an uniform program will be helpful, especially where our organization is weak. Part I is an outline of general subjects. Part II is this outline filled by the county committee, with subjects and each subject assigned to a member of the county society, (or chosen by the members). If the State Association will prepare Part I and after Part II is completed by the county committee, have it printed for use by the county society, the work will be strengthened and the membership increased.

The real value of membership should be emphasized. The JOURNAL has become one of the best; alone worth the cost of membership. Medical Defense is many times worth the membership fee. Insurance examinership often depends on membership. The social fea-

tures are valuable. Most important is the scientific study implied by membership. These items should be printed on the cover of the program as constant reminder. The one essential thing for a county medical society is a printed program for the entire year. This should be mailed as a one-cent letter before each meeting as notice of the meeting. It will also keep the work of the year constantly before the members. Good work will increase the membership. An organizer to visit each county society and spend a few days soliciting members would be very helpful. The increase of fees from new members would more than pay his way and salary.

Recent years have brought to us some wholesome legislation. Since laws are seldom enacted in advance of public sentiment, we conclude that there is a growing sentiment among the people for these things. Back of it all our profession is an essential part.

In 1909 this Association adopted the following: Prevention, management and treatment are the individual and social requirements of tuberculosis. The object is a well-planned, up-to-date tuberculosis infirmary in every county in the State; built by each county; owned by each county; controlled by each county; and with laws which secure protection of patient and people from further spread of the disease; and with facilities for treating the curable and caring for the incurable. In 1912 a law was enacted making this possible. Obnoxious bills have been vetoed at our request. In perfect organization we have power for good. Leaders will rise up and crystallize and utilize all the sentiment we can create. Other good things have been realized—an anti-tuberculosis commission and an appropriation of \$10,000 annually; \$30,000 annually for the State Board of Health; an individual drinking cup law, a vital statistics law, a bacteriological laboratory, a state institute for health officers; three (3) Rockefeller men doing hookworm work; and the people in accord, indeed in many places leading in this work.

When the Commission has instituted an infirmary in approximately every county in the State; when vital statistics are the basis of scientific work; when our bacteriologists have attained their highest usefulness; when health officers are paid for their entire time and are placed under civil service; and when the State Board has had a few more years like 1912, in dealing with hookworm, pellagra, tuberculosis, typhoid fever, and other preventable diseases, then, with the momentum which success always adds to an undertaking, *we shall see grand things indeed in Kentucky.*

We shall not assay the praise of the superior doctors of Kentucky. Many illustrious men have lived and become a part of our his-

tory. Many more who are equally praiseworthy live and work to-day. I make mention of one class who seem to have been overlooked, *the village doctor*. This class has many worthy representatives among us to-day. I take liberty to mention three, Drs. J. W. Cooper, President of Henderson County Medical Society, J. W. Ellis, our Delegate to the American Association, and C. Z. And, who has had every honor which we can bestow. These are Christian gentlemen. Their families are an honor to their communities. They are men of large estate. They give high-grade service, professionally and otherwise, to their people. They are men of the highest type; and they represent the best there is in life. A study of this class of physicians by men who are entering the profession would stay the mad rush to the cities where so many are eclipsed and lost sight of, and where their families are heard of no more.

We have purposely made this deliverance somewhat of a message to the State Association. We have discussed, the village doctor, legislation, membership, organization, compensation, future work, department of health, the year 1912 and given our salutation.

We now revert to the optimism of our introductory paragraph. The front page of the modern newspaper does not reflect the real condition of modern life. The crime and misconduct recorded thereon under glaring headlines is but one in a thousand. In smaller type, and in obscure corners, if at all, is the record of the life that you and I, and a great majority of our fellows are doing our best to live.

If in our State a few doctors are unfaithful to the tenets of our profession, this should not discourage us. Rather let us remember that 3,500 other doctors are true men in every sense of the term, and capable, and trustworthy. *We look with cheerful faith upon a triumph to-morrow.*

ORIGINAL ARTICLES

TUBERCULOSIS WORK IN EUROPE.*

By J. W. PETTIT, Ottawa, Ill.

The Irish have an expression that "far off cattle have long horns" which is only another way of expressing the thought that "distance lends enchantment to the view."

Because European countries are older and more particularly for the reason that many of them have been engaged in the warfare against tuberculosis longer than we have in this country, we have very naturally looked

to them for leadership and assumed that their methods were right and have blindly followed them without question. This attitude on our part has led us into serious blunders. This assertion is based upon a recent investigation of tuberculosis work as it is being conducted by our transatlantic brethren and applies with peculiar force to our slavish adherence to European standards of architecture in the construction of tuberculosis sanatoria.

The statements herein made are based upon definite data and the criticisms are unprejudiced. I found that while we have an exaggerated view of the progress they have made, they likewise have a distorted view of our work and in both instances, the mistakes which each have made have been overlooked, and the really meritorious things done have been magnified. Viewed at close range a better perspective is gained, and defects observed that could not otherwise be discovered.

I had already made quite a thorough investigation of actual conditions in this country, particularly from the sanatorium standpoint and found there was much knowledge that could not be gained by personal investigation.

The primary object of my recent visit to Europe was to investigate actual working conditions, particularly from the standpoint of sanatorium construction and treatment, and incidentally to attend the International Tuberculosis Congress at Rome. What I have to report is a report upon the conditions as I found them, based upon rather an intimate personal experience with the work in this country.

Until within the past year Germany has taken the lead, not only in scientific work, but in provision for sanatorium treatment. Germany has more sanatoria and has made greater advance in prevention and placing the early cases under treatment than any other country in the world. During the past year Great Britain has passed what is known as the National Insurance Act out of which is appropriated \$7,500,000 for tuberculosis work alone. The plan proposed is the most comprehensive thus far attempted by any government, and the appropriation larger. The act provides for compulsory notification, sanatorium treatment for the curable, hospital care for the incurable, regulation of milk supply, partial support of family during invalidism, special provision for infected children, increased attention to education along health lines in schools and colleges, and better houses for the poor. The total amount of funds available for this whole scheme is \$12,000,000 for the first year, which on a per capita basis would be equivalent to about \$30,000,000 for a like schedule in this country.

*Read before School of County Health Officers, Louisville, 1912.

The Committee which has been appointed to work out the plans in detail recommend among other things that a dispensary be provided for each 150,000 of urban population, and that sanatorium provision be made on the basis of one free bed for each 5,000 of population.

Perhaps a better idea of sanatorium conditions can be obtained by giving a detailed report of a few of those I visited.

Mt. Vernon, Northwood, England, accommodates 150 patients. None but early cases admitted. The outlay very elaborate and extravagant. Total cost \$6,000 per bed. Built by rich diamond miner of South Africa. No endowment and must be supported by subscription. Magnificent buildings and grounds including large and well lighted laboratory, but no equipment to speak of. Can only do ordinary routine work. Treatment only hygienic. It is a serious question whether this institution can be maintained much longer by public subscription.

King Edward Sanatorium, Midhurst, 65 miles from London. Built by rich friend of King Edward the VII., who allowed the use of his name without knowing the plans in advance. No one knows how much it cost, but reputed to be not less than \$10,000 per bed. King Edward did not know what had been done until he was asked to dedicate it. It is said he was amazed and outraged when he saw what had been done in his name, and only barely repressed publicly expressing his disapproval. In private he did not hesitate to say that it was a piece of stupendous folly, and regretted exceedingly that his name should bear the odium of being connected with it. This is one of the English institutions which is most frequently referred to and which has been accepted as the ideal standard by many who are not familiar with the facts. This sanatorium is in reality a monument to the King and only incidentally for the cure of tuberculosis. It is the most conspicuous example of extravagant folly in the whole history of the tuberculosis movement.

Frimley Sanatorium, Sussex County, Adjunct to Brompton Hospital, London. Located three miles from railway station in pine woods. Rough, unproductive land. Location unsightly. Built very much on same lines as Mt. Vernon, Northwood, only not so expensive. Cost about \$3,500 per bed. Graduated labor distinguishing feature. Apparently logical, and made possible because none but early cases are admitted. Institution new. Grounds rough, making vast amount of work necessary. It is questionable whether the plan of graduated labor can be conducted after improvements are all made as the land is not suitable for farming excepting at enormous expense for subduing and fertilizing.

Benenden Sanatorium, 65 miles from London; for industrial classes only. Eight miles from railroad. Unforbidding location. Buildings economically constructed, costing, including land and equipment, \$750 per bed. Graduated labor. Mostly farm and garden work. None but incipient cases received. Treatment up to date so far as finances will permit. Model institution of its kind and the only one in Great Britain built along economic lines.

There are numerous small sanatoria throughout Great Britain both private and public but none of them doing more than ordinary work. Private sanatoria are for the most part rather cheap affairs doing crude work and conducted more on the boarding house plan than as scientific sanatoria. The institutions specified, particularly the more expensive all have good laboratories, but little or no equipment or funds to conduct them. The same is true of maintenance in every particular. The King Edward and Mt. Vernon Northwood, are instances of rich nabobs glorifying themselves by erecting monuments to themselves under the guise of philanthropy and letting the institutions struggle for an existence.

There is no factor in the treatment of tuberculosis either from a scientific or economic standpoint of more importance than sanatorium architecture and none which has received less attention or in which more unscientific and economic blunders have been made. England copied Germany's mistakes and we have copied the mistakes of both countries. The most serious and expensive mistake which has been made in the tuberculosis propaganda throughout the world is in the irrational and extravagant expenditure of money in the erection of massive buildings for the treatment of tuberculosis. The public have become so accustomed to every philanthropic outburst being associated with some palatial building that it is high time we should urge that the current of philanthropy find expression in the modest and comprehensive scheme of practical medical men, rather than in the grand and ambitious methods of the builders.

It is a strange anomaly that charity patients are in many instances provided with better accommodations than even the well to do could afford if these institutions were conducted on a business basis. Such a plan is as irrational as it is unscientific, and has a tendency to break down the whole system by unnecessary expense and it is to correct just such mistakes as have been made, and will continue to be made, until the public have a better understanding of the necessities of the situation, that makes it necessary in connection with the tuberculosis propaganda to conduct a campaign against such extravagant

and irrational methods of applying the treatment. There are other large expenses connected with the campaign against tuberculosis and all the funds at our command should not be exhausted in building sanatoria which is only one factor in the warfare. Where there are so many things to be done we should conserve our resources. They certainly should not be exhausted or wasted in the construction of buildings, which are not only not needed but are worse than useless. Thus far in all countries sanatoria have absorbed the major part of the funds appropriated, leaving little or nothing for anything else, not even the support of the institutions themselves.

I would not feel so free to criticize after having been treated so courteously by the officials of these several institutions were it not for the fact that I find that those in charge as well as physicians and sanatorium officials everywhere are unanimous in their condemnation of this extravagant expenditure. This being true, it is interesting to know how the custom became established.

Brehmer, Detweiler, and other pioneers in the sanatorium movement, although advocates of fresh air, at first had rather crude and imperfect ideas as to its application which led them to make many mistakes judged by present standards. One of these was to follow the conventional hospital plan of architecture. As a result all the earlier institutions are massively built and only with a view to applying fresh air during the waking hours. As the movement progressed medical men saw that the massive building was irrational from a scientific standpoint, and set about to devise simpler styles of architecture. This has necessarily taken a number of years to accomplish and there is much yet to be done before ideals are reached. In the meantime the tuberculosis sanatorium became more popular. The demands of the situation became more and more apparent with the result that philanthropists came to the aid of many communities in supplying all or part of the funds necessary for their construction. Instead of consulting practical sanatorium officials and keeping pace with the rapid progress made, they invariably placed the construction of these institutions in the hands of architects who knew nothing of the scientific demands of the situation with the result that palatial monuments to the donors have been erected, instead of sanatoria for the sick. The result has been to establish standards that others have blindly followed on the assumption that practical men were responsible for this style of architecture, hence it must be necessary. It is a serious question whether or not these so-called philanthropists have not done the cause more harm than good.

The problem of housing tuberculous pa-

tient is so new and radically different from the housing of any other class of patients that it is not surprising that those charged with the responsibility for the expenditure of public or private funds are at a loss to know how to proceed. These men are usually laymen and very naturally the first step they make is to visit institutions already in existence. These have for the most part been unnecessarily expensive. The result is that these mistakes are duplicated where there are sufficient funds at their command, or the whole plan is abandoned where there is not.

An illustration in point. Five years ago the legislature of a neighboring state made an appropriation of \$75,000 for a State Institution. The Board of Control was composed of three intelligent laymen. They had absolutely no conception of how to proceed, and very naturally visited some of the elaborate institutions in our eastern states. They found that no state had an institution that had cost less than \$250,000 and many of them much more. The same was true of other sanatoria whether public or private. They had had great difficulty in securing the apparently modest sum of \$75,000 and knew that it was utterly useless to attempt to secure a larger appropriation, hence were about to abandon the whole enterprise. I was consulted, and insisted they had sufficient funds to make a good beginning if expended properly. They were advised to construct simple, inexpensive buildings. This advice was followed and within less than a year they had an institution in operation for the accommodation of 100 patients at a total outlay for lands, buildings, and equipment, of \$90,000. With the experience since gained, I am sure this institution could have been duplicated for even less. We are indebted to an English physician for suggesting the sanatorium treatment; to the Germans for systematizing it, but it is left for the practical Americans to simplify it and put it on a more economic basis.

If any of these extravagantly built institutions had been endowed with what has been spent uselessly in buildings it would be amply sufficient to support them liberally and still allow a good margin for scientific research. This wasteful extravagance is the result of the dominating influence of the men of money over the men of science.

The application of our present knowledge of tuberculosis is practically a new proposition, and it is to be expected that the inventive genius of the American will work it out to better advantage than the less inventive and less adaptable Europeans. As a matter of fact the Europeans freely confess that in all problems involving organization and adaptation, we are expected to lead.

While there is practical unanimity through-

out the civilized world as to the treatment of pulmonary tuberculosis, there is a radical difference between methods of treatment of the so-called surgical forms of tuberculosis in Europe and the United States.

In Europe, especially in France, and Germany, quite as much attention is paid to closed and surgical tuberculosis as to the pulmonary form of the disease, while in this country this class of cases is practically neglected. The treatment in Europe is almost exclusively hygienic and dietetic. Operative procedures are only resorted to in exceptional cases. For example in one institution of 1,100 beds exclusively for children under fifteen years of age, I was informed that not more than six cutting operations had been performed in the past three months. These institutions are usually located along the seashore. One illustration will suffice for all.

Berk Plage, located on the north shore of France, 35 miles from Calais, splendid beach, wide expanse of sand, village of 10,000 people which includes 4,000 cases of surgical tuberculosis. Supported by the City of Paris. Plan of buildings good. While substantial not necessarily expensive. Abscesses are aspirated and injected with iodoform. Glands are never operated upon unless discharging and then are merely cleaned out thoroughly and dressed antiseptically. Operations on long bones more frequent, but only then when there is extensive necrosis or abscess formation. Operations radical when indicated. Plaster casts in suitable cases.

There are several charitable institutions located here and hundreds of private patients flock to this village from all parts of Europe who for the most part live in pensions. A novel feature of the treatment is the earriages constructed especially for patients in casts which permits them to move about even when compelled to constantly maintain a prone position.

In Switzerland, Germany and Italy, there are many institutions for the treatment of surgical tuberculosis particularly in children, and the results of treatment are very satisfactory. In France the virtue of the treatment is supposed to reside in the sea-air, in Switzerland, the mountain air, while in Germany and Italy, it is simply air. It is well known that in this country about all we do for our surgical cases is to operate upon them and place them in the wards or rooms of a general hospital. My personal opinion is that we operate too much, and they operate too little, and that the best results would be obtained by supplementing the surgical skill and technique of the American surgeon with the hygienic-dietetic, tuberculin and vaccine treatment of the Europeans. They occupy one extreme, and we the other. It seems rea-

sonable to assume that the truth lies somewhere between the two extremes. At any rate their results are certainly far superior to ours.

*The International Congress on Tuberculosis was held in Rome, April 14th to 20th, 1912. There was no striking discovery presented at the Congress similar to that of Robert Koch when he announced the non-identity of human and bovine tuberculosis. There was very little of what can strictly be called original work, and none of it of epoch-making importance. The suggestion which attracted the most attention was the discovery of the relation of bovine and human tuberculosis. This was discussed very thoroughly in the convention which preceded the Congress proper, and the discussion was participated in by the master minds of the leading European nations. The discussion was characterized by eminent fairness and a disposition on the part of all to arrive at the truth. During the past three years and a half numerous investigators have been at work upon this very important and very practical problem, and while the leaders are not yet in perfect accord they are much nearer together than they were at the last Congress,—near enough at least to make it possible for them to agree unanimously to the following resolution:

Resolved, First, the prophylaxis against tuberculosis must principally be directed against the suppression of contamination from man to man and principally in the family.

Second, the contamination of man by bovine infection is of less frequency, nevertheless it is necessary to continue all measures against infection of bovine origin.

By way of explanation it may be said that this is a compromise resolution and really represents the conservative view still held by the German school, who, while willing to admit the infection of man from bovine sources, does not regard it as a serious menace. The English and Scandinavian investigators regard it as a serious menace, with the French occupying a position somewhere between these two extremes. In the discussion there were certain local conditions brought out in the several countries which may account for the differences in the findings of the several investigators. For example in Germany and France milk is usually cooked, while in England and the United States it is usually taken raw. There also seems to be more bovine tuberculosis in some countries than others, and especially in the colder climates, and also more tuberculous cattle in different localities

*Taken from author's report of International Congress on Tuberculosis for the Journal of the American Medical Association.

in the same country. It may be found later that these local conditions have an important bearing in certain localities and if so it will tend to fortify and strengthen the views expressed in the resolution.

The work of the British commission may fairly be regarded as the most reliable. Their work has been far more comprehensive and open-minded. The British Commission have no pre-conceived views but are simply seeking the truth, while the German school are apparently followers of Koch, and seem to be seeking to establish his views rather than to arrive at the truth.

The suggestions that attracted most attention from the standpoint of treatment was a revival of the method of treating unilateral pulmonary tuberculosis by the production of artificial pneumo-thorax, certain aspects of immunity, and heliotherapy. It was significant that very little was said on the influence of climate *per se* in the treatment of tuberculosis, except surgical forms in which the French insist upon the virtues of sea air, while the Swiss insist just as strongly upon the specific influence of mountain air and sunlight. Inasmuch as they are all securing substantially the same results, it is fair to assume that the final conclusion will be, as in the treatment of pulmonary tuberculosis that the virtues of their methods consist in fresh air and sunshine rather than any peculiar attributes either of sea or mountain air. Both nations are to be congratulated upon their excellent work in this important and much neglected branch of the work. The United States seems to be behind all the leading European Nations in making provision for the scientific and systematic treatment of surgical tuberculosis.

While but little that is new of definite value was developed by the Congress, it was interesting to note the decline of former views with regard to the influence of climate and the growing sentiment, not only in favor of sanatorium treatment, but the further fact that the results by other methods are unsatisfactory.

The hygienic and dietetic treatment of tuberculosis is accepted in Europe as fundamental and whatever changes are made in the future will be with the present methods of treatment as the basis. The use of tuberculin as a diagnostic and therapeutic agent is no longer questioned by those in a position to speak authoritatively. Vaccines and serums are regarded with favor, but are still in the experimental stage.

A dominant note of the proceedings was that instead of looking for a specific remedy for tuberculosis, the protean character of the disease was recognized, and instead of directing our energies to the discovery of a single

remedy or method, intensive study is being focused on the several methods which must be devised to meet the varying conditions.

If nothing new of practical value was developed, the work of the Congress was none the less notable. Several new lines of attack were developed, and while practical results have not been obtained, the indications are that some of them will prove successful. Be this as it may, the most encouraging feature of the Congress is shown by the activity which must result in vastly improved methods of treatment, as has hitherto been done in other diseases, which seemed as formidable as tuberculosis now does.

In all the countries of Europe they have passed through that period of over-enthusiasm as to results of treatment through which we are now passing, and which is so discouraging to practical workers in this country. The sanatorium has taken its proper place in the fight against tuberculosis and sanatorium physicians are not embarrassed by being expected to accomplish more than is possible and criticised because they do not meet the demands of an over-enthusiastic public.

In the matter of governmental control European nations and especially Germany and Great Britain are far in advance of the United States. In the matter of social organization we are in advance of them, and the outlook far more favorable for effective work in the future. This is perhaps due to the difference in political and social conditions. It is easier to enforce police regulations in European nations because their forms of government are more paternal. On the other hand it is easier to inaugurate and conduct social movements in the United States for the reason that we do not have to overcome the class distinctions which obtains in even the most liberal European nations. It is generally believed, even by Europeans themselves, that more can be accomplished by education than by legislation, although each must supplement the other, hence our transatlantic brethren are looking to us to take the lead in this great warfare which for the most part must be conducted along educational lines.

CONSTIPATION.*

By J. C. McCREARY, Cave City.

Constipation is an unnatural prolonged retention of the feces in the alimentary canal; a retarded defecation; or we might term it a symptom arising from a variety of morbid conditions of the intestines and not a distinct disease of itself. The term is a relative one, strictly natural law governing intestinal

*Read before the Barron County Medical Society.

evacuation in the human species requires one, two, and sometimes three, discharges every twenty-four hours; on the other extreme some may enjoy excellent health with one movement a week or if the diet has consisted of chiefly fluids and absorbed, one a month.

ETIOLOGY.

General—(a) temperament, (b) habit, (c) diet, (d) bodily weakness, (e) exercise and prolonged diuresis and diaphoresis.

Local—(a) atony of the abdominal muscle, (b) atony of the large bowel, (c) pressure by tumors, (d) intestinal stenosis, (e) congenital stricture.

Temperament: I have been much struck with the part that temperament plays in constipation. If you will carefully scan over your constipated patients you will not fail to observe that the majority of them are of a nervous, bilious temperament of the dark or brunette type, anemic, pale skin, dark hair, torpid liver.

Habit: Found most frequently among those leading a sedentary life by which natural calls are irregularly attended to or neglected is sure to lead to an over-distension of the lower bowel and rectum, and is a common cause of chronic constipation. Among the females we have the false modesty that prompts postponement and suppression of all desire to defecate, especially in public places, also the habitual, hurried performance of the act, in cold illy-kept closets; all of which has a tendency to obtund the sensibility of the bowel to fecal matter contained therein. This accumulation in turn causing an overdistension, a hardening into scybalous masses, difficult of expulsion.

Diet: Diet plays an important role in the cause of constipation. A constant and continued use of concentrated articles of food, such as meat in which there is little residue left to stimulate the bowel to peristalsis, again the diet may be of such a very coarse variety, and leave an excess residue and cause impaction of the bowel.

From obvious mechanical reasons, it is necessary that there be a certain bulk or volume of fecal matter, in order that the intestine, the colon in particular, may easily grasp and propel it along to its destination; and for similar reasons, a too small amount of food, even though it be of proper composition, will produce the same effect. Constipation may arise from the too scanty taking of fluids, whereby the feces become dry and hard, lacking the smoothness which normally enables them to glide along the mucous lining of the intestine without friction. Overloading the bowel with food of a bulky and coarse nature may produce constipation by overdistending and weakening the intestinal tube. Beverages

that contain tannin, such as tea and the red wines have a tendency to lessen the intestinal secretions and produce constipation. Negligence in the regularity of eating and defecation, imperfect mastication, sudden changes in the quality, and the quantity of foods. Most fevers are attended by constipation, on account of the diminished secretion of the digestive and other fluids which are common under these conditions.

Bodily Weakness: Constipation will bring about general bodily weakness, hysteria, neurasthenia, spinal cord affections, hepatic disorders, jaundice, and an habitual dependence upon the use of purgatives.

A prolonged and excessive action of the kidneys and sweat glands may rob the bowel of its necessary fluids and cause constipation.

Local Causes: Constipation may be due to a weakened condition of the abdominal muscles on account of which the voluntary expulsive efforts of defecation can not be made; of such, we might mention, during pregnancy, obesity and abdominal tumors. There may be such local conditions, as to prevent the emptying of the rectum, by causing pain, with consequent reflex spasm of the sphincter; of such we might mention, fissure of the anus, inflamed hemorrhoids, ulcer of the rectum in or near the anus, irritable and inflamed prostate gland, a tender and prolapsed uterus in a female.

The depression of the abdominal and pelvic viscera down upon the rectum by the present well known habits of dress among the females is one of the causes why women suffer more from constipation than men. There is a form of rectal constipation existing among females, which has received too little attention; it is that form caused by the pulling down of the recto-vaginal septum, thereby forming a pouch in the posterior vaginal wall which constantly increases in size, changing the direction of the intra-abdominal rectal pressure to the vagina instead of the rectum. Making it difficult for the rectal sphincters to relax so as to void the contents of the bowel; the result of which is an incomplete defecation.

There may be tumors located along the intestinal tract of sufficient size to be plainly palpated, bimanually, and this condition cause constipation. Constipation may be the result of a pyloric stenosis, the result of the limited amount of food entering the intestine, but in this condition the vomiting which usually accompanies it is sufficient to direct attention to the stomach. The most important and we might say the most serious condition which might be indicated by constipation is intestinal obstruction. An obstinate case of constipation not yielding to the ordinary and appropriate remedies should arouse a suspicion, and especially when associated with

nausea, vomiting, distention of the bowels, and abdominal pain. Having spent sufficient time on the etiology of constipation we will now pass on and give you the leading symptoms, classing them under two heads, direct and reflex.

Direct or local symptoms are experienced by a sense of fullness, weight in lower part of bowel, and perineum, flatulence, pains of a colicky nature, sometimes alternating with diarrhoea, occur frequently. The calls of nature are often attended to hurriedly not completing the act, the bowel is only partially emptied by the movement, then we have a sense of fullness, the complete relief not experienced.

Reflex: Reflex symptoms are headache, irritability of temper, malaise, languor, hebetude, palpitation, flushing of the face, vertigo, menstrual troubles in women, sleeplessness, bad dreams, neuralgias, coated tongue. If the abdomen be palpated you may be able to locate fecal tumors at the hepatic splenic, and sigmoid flexures, of hard, round, doughy-like masses.

PATHOLOGY.

If permitted to continue for a time, we will have an irritation or inflammation of the mucous membrane coming in contact with the retained feces, causing temporary diarrhoea, with pain and tenesmus but the more frequent result of constipation is the formation of a septic material, and its absorption, creating a degree of autoinfection, accompanied by feelings of depression, loss of appetite paroxysms of sick headache, and vertigo.

PROGNOSIS.

When constipation is the result of intestinal obstruction, the prognosis depends altogether upon the nature of the obstruction, its removal or curability. When it depends on the weakened condition and loss of peristaltic action brought about by the patient's erroneous habits of life, the prognosis is good provided the habits of patient can be permanently corrected, otherwise the relief will only be temporary, and relapses will soon follow.

COMPLICATIONS AND SEQUELAE.

The complications you are all familiar with; hemorrhoids, fissures, mucus and ulcerative colitis, perforation, and enteritis, in old people enteroliths, or calcified scybula, hernia from violent straining, intestinal obstruction, and cerebral hemorrhage.

TREATMENT.

We now come to the treatment which I propose to place under three heads: Hygienic, drugs and mechanical; I would again subdivide the hygienic into, habits and diet.

First of all the causative factors, should receive our attention, and be removed, modified

or lessened. Have our patient to establish a regular time and frequency of going to stool, let this be the time of day that best suits the individual case, but when that hour comes let nothing interfere. Attention to the calls of nature should be considered a duty, and proper time and attention must always be given to the completeness of the act.

You will observe that all young girls especially need instruction along this line. A sufficiency of bodily exercise is imperative and let that be such as affects the abdominal muscles, and in the males I know of nothing better suited to the case than the use of the old fashioned buck-saw, this in addition to exercising the arms, is an especial stimuli to the muscles of the abdomen.

Diet: Instruct your patients to eat the proper food and in the proper manner. Eat a great deal of fruit and such articles as contain irritating undigestible residuum, should be the ones chiefly selected. I would especially recommend oatmeal, corn meal, and the unbolted wheat flour, raw prunes, figs and dates are all excellent if thoroughly masticated. A pint of cold water drunk regularly at bedtime and in the morning before breakfast are very efficacious. How strange and singular it is that "Beauty Specialists" have not yet found out that the daily evacuations and the morning cold bath, with open air exercise, are worth car loads of cosmetics, paints, powders, pastes, massage, etc., which they advertise so loudly in our daily papers, for the complexion. We all know that there are no cosmetics that can remedy a blotchy, muddy, pimply complexion, and there is no tonic that will bring the bloom of youth to the woman who is constantly absorbing into her blood, the impurities and liquid portions of her feces from her alimentary tract.

Drugs: Drugs occupy a subordinate position in the treatment of habitual constipation. The constant use of laxatives or purgatives only tends to make conditions worse, and at last an ultimate resistance to the actions of cathartics at a time when circumstance would really require their use.

Drugs employed to unload the bowels, may at times be used, but let it be sparingly; the mildest forms being selected.

Constipation is only temporarily relieved by cathartics, and their frequent use only tends to render the bowel accustomed to their action; it being a well known fact, that when once this dependence upon drugs is formed, larger and larger doses are required, until the patient is unable to have a passage without first taking a handful of pills and they of the most powerful cathartic group and enormous doses. It is upon this principle that fortunes are made by the makers and sellers of the patent medicines, that are continually be-

ing displayed in our daily, weekly and Sunday papers, the effects of which you are also familiar with.

The indications for treatment should be very simple; open the bowels and see that they are kept open daily, by as little help as is necessary, until you have a habit established sufficient to restore the organs to their normal functions. The remedies that I have found most efficient in my ten years of practice are the laxative granules composed of the following drugs, aloin, atropine, oleoresin capsicum, emetin and bilein. The therapeutical effect of each drug being particularly indicated in the treatment of constipation. In aloin we have a stimulator of peristalsis, and most especially affecting the muscle fibres of the rectum, the dose never exceeding half a grain. Large doses do harm and you never get the tonic effect that you need, but exhaust and create an irritability by over stimulation. Strychnine is also a stimulator of peristalsis and the nerves of sensation lining the mucous membrane of the bowel, and thus rendering it less tolerant of the contents, thereby affording more power to throw it off.

Atropine overcomes the tendency of the aloin and strychnine to produce griping. It also favors and assists their laxative action by producing a paralysis of the terminal ends of the nerves. Since atropine lessens secretions it becomes necessary that we add something to overcome its effect in that direction, hence we add emetine, which is a stimulator of secretions, and this is especially needed if the stools are inclined to be dry or costive. Capsicum is also included also as a stimulator of secretions and to increase the sensibility of the mucous membranes. I have many times used the above remedies without the capsicum but never with as good results. In bilein we have a liver stimulant and eliminant, and it is also a stimulator of peristalsis. The manner of giving these drugs is a very important one. You should begin by giving a sufficient number of the granules to produce one daily evacuation of the bowels; now divide this quantity into three equal parts, one part to be taken before each meal.

After a few days it will be found that the number in each dose can be reduced somewhat and as the bowels become stronger and habit of regularity well established, the number of granules at each dose is gradually lessened until one will produce the desired results, but I think it well to continue the one for some length of time, more for its moral effects than anything else that it might accomplish. In fact in some cases it is well to give a placebo to some patients for a time, so strong is a pill fixed in their mind with the movement of their bowels.

If the above suggestions be carefully car-

ried out you may expect to cure your patient of constipation.

Mechanical: As to mechanical means, I wish to say but little, since I consider the most of them harmful. Enemata is injurious if long continued, by reason of its irritating effect on the mucous membrane, of course they have a temporary use, when we have a weak irritable stomach, or wish to relieve a loaded bowel or flatulence. Suppositories do but little permanent good. Dr. Hirschman mentions a method of dilating the rectum and lower bowel by means of a bladder like rubber sack introduced into the rectum as high as possible, allowing the stem end to extend outside the rectal orifice, and to which is attached an ordinary syringe bulb, and by this means the bag is inflated until it gives the patient discomfort or to the point of tolerance and remains in that condition for five or ten minutes when the air is allowed to escape, after waiting a few minutes repeat; this treatment is repeated daily for from five days to a week, when he states that usually after about the second treatment the patient will have a small unaided action from the bowel, and each day following a slightly larger and more satisfactory stool. When the defecation approaches normal the treatments are given only on alternate days until finally left off altogether, he reports some excellent results.

Massage: Massage has a right to claim an important part in the relief of constipation when properly carried out. It acts by stimulating peristalsis and the abdominal muscles and when employed should be given at a certain time of day and preceeding the time for a desired evacuation of the bowel. Massage stimulates abdominal circulation, dispelling certain passive congestion, increases the muscles in volume and strength and is the best curative agent for constipation from muscular paralysis not due to central nervous diseases, best curative agent for constipation due to anesthesia due to local causes, but is contraindicated when the constipation is due to inflammation or tumors.

My paper has been prepared, assuming the constipation to be in adults, the subject is too lengthy to include children which require in most cases, an entirely different treatment and is worthy of a paper relative to them alone.

RHEUMATISM IN CHILDREN.*

By J. F. DUNN, Arlington.

Rheumatism is a constitutional disease, marked by inflammation of the connective tissue structures of the body, especially the muscles and joints, and attended by pain in the joints or muscles. It affects all classes of people, both sexes and all ages from infancy to the extremely old; however, it is much less frequent or severe in children perhaps from the fact that they are not subject to so much exposure as adults.

In children, of which this paper treats, it rarely occurs in the first few months of life, or else we fail to recognize it. There are a few cases on record that were found at nine months of age and possibly a little earlier still. It is more prevalent from the 5th to the 10th years. It is also more frequent in the damp, cool season of the year.

Heredity plays an important part in the etiology. Children whose parents have had rheumatism are more commonly and more severely attacked than others. It is found frequently among those who have poor hygienic surroundings and are ill-clothed and fed. Large families that live in small tight houses and are deprived of their allowance of pure air are very susceptible.

SYMPTOMS.

Unlike adults—the symptoms in children are, as a rule, very mild, in fact, so mild that if we are not very watchful we are liable to overlook it and serious complications may arise.

Not many joints are affected, it being confined principally to the ankle, knee and wrist joints. Pain and swelling are slight and redness is usually absent.

The child has a little fever, usually ranging from 100 degrees to 101 degrees, cries and favors the affected joint or limb and cries out when the affected part is touched. Occasionally the patient has no fever and the only symptom is pain and tenderness in the joint. Children that cry with the knee-ache at nights should receive careful attention, however trivial this symptom may seem.

This disease is in itself not dangerous, but the one complication, especially, which the object of this paper is to bring out, viz.: endocarditis, which cometh like a thief in the night, should cause us to stand as guards over our little patients almost constantly from the time the first little knee-ache appears till their systems are perfectly free from any sign of rheumatism. This complication is a very common one and Koplik says its absence is rare. It is often overlooked and may be

detected by auscultation and later by inspection and palpation. On auscultation the mitral regurgitation may be heard which consists of a blowing systolic murmur at the apex of the heart, often transmitted around the left side of the chest to the back and is heard at the time of the radial pulse beat. Later on, inspection and palpation reveals the dilated condition of the heart.

There is no immediate danger connected with this condition, but if left alone it gradually grows worse and chronic valvular disease results, finally becoming serious and endangering life. Therefore, it is of the utmost importance that this condition be recognized early and corrected.

Other complications may arise, for instance chorea. This is closely associated with rheumatism as well as endocarditis. In fact, Holt says that when you have any one of the three conditions—chorea, endocarditis or articular symptoms, always look for the other two.

Tonsillitis and torticollis are believed to be of a rheumatic nature. I had a case of tonsillitis last winter in a boy six years old, followed by torticollis. Some of you saw the case last spring. I believe it was of rheumatic origin, however rheumatic treatment had very little effect although it was not continued very long as he fell into the hands of an osteopath. The case is of nine months' standing and is no better at present.

DIAGNOSIS.

It is an easy matter to diagnose a case of rheumatism in an adult, but in a child it is not so easy. By using good common "horse sense" and drawing on our imagination we can generally recognize it. We should inquire into the family history as heredity plays such an important part.

The trouble has to be differentiated from tuberculosis of the joints, in which case it is confined to a single joint. The onset is slow and gradual and covers a considerable period of time, with no remission or intermission of symptoms. The case gradually goes from bad to worse, while on the other hand, in rheumatism the onset is usually sudden and the symptoms last for two or three weeks and then disappear or lessen in severity, even without treatment only to be repeated later and becoming worse in damp weather.

The history of previous attacks of articular symptoms, of tonsillitis or torticollis aid us considerably in the diagnosis. There are two symptoms that are certain diagnostic features, which, when present, will always exclude tuberculosis, viz.: 1. Involvement of other joints. 2. Endocarditis. Whenever you have these two conditions in connection with articular pains you may rest assured it is one of rheumatism.

*Read before the Carlisle County Medical Society.

This disease is more often overlooked entirely than confounded with other diseases. This is where the danger lies. The little patient comes to us for relief and we perhaps in a hurry give them only a passing glance, pronounce it growing pains and let them go, telling the mother they will outgrow it. This occasionally proves to be a serious mistake. I often think of a statement Dr. Stuckey made to our class while in college. He said, "Boys always examine your office patients carefully whether you are looking for anything or not, they appreciate it, and often you will find conditions you least suspected." This rule "holds good" in rheumatism, especially.

PROGNOSIS.

The majority of cases get well, even without treatment, but occasionally the cardiac condition develops which could have been prevented, had we only given them the benefit of the doubt. I would much rather be guilty of giving a bunch of little fellows some medicine they didn't need than to neglect them and, through my negligence, one of them develop conditions that would perhaps cause years of suffering and may be death.

TREATMENT.

Having diagnosed our case as one of rheumatism, we should, however mild the case may be, put it on active treatment at once. Even in the mildest of cases much mischief could be going on in the heart.

The diet should consist largely of milk and foods containing little or no starch. They should be kept in the house in damp weather and comfortably clad the year around. Give them plenty of fresh air and sunlight. If the child has any amount of fever keep it in bed until it is normal.

Holt says that absolute rest and equable temperature are unquestionably of more importance than anything else in protecting the heart during a rheumatic attack. Salines should be given freely. In fact the medical treatment is about the same as in adults, salicylates in some form, alkalies and free catharsis.

During convalescence and between attacks general tonics should be administered, such as iron, cod liver oil, etc.

The little fellows have enough aches and pains at best, henceforth, let us always be on the alert, examine our little patients carefully, watch them closely from day to day and at the end of our toilsome journey we can look back with the sweet assurance that our medical lives have not been a complete failure.

REPORT OF A CASE OF HOOKWORM.

By ELDRED A. DAVIS, Earlington.

I wish to report a rather peculiar case of complete night blindness, probably caused by hookworm infection.

Alex S., day laborer, age 32, American, married, family history negative. Well developed case of hookworm infection. Greatly emaciated, progressive loss of weight from 160 lbs to 110 lbs. Infection of probably several years standing. Marked bulmia, ground itch on hands, reflexes diminished, chest normal, abdomen distended, occasional diarrhoea, urine showed no albumin or sugar, no pains about the body, no swelling of hands or feet.

Patient could not see, except on bright sunny days, had not seen stars or moon in three months, could not move about at night or cloudy dark days. After ova was found in feces, thymol was administered in the routine manner 60 grs. and two weeks later 40 grains more were given.

Symptoms began to subside and patient resumed work, increased in weight, and suddenly one night after the second dose of thymol vision returned. Patient is still gaining and has normal vision at night.

I report this case in hopes that some one can offer some explanation, as I can find nothing on the symptom in literature.

THE FORUM

REPORT OF DELEGATE TO THE NATIONAL CONSERVATION CONGRESS.

By V. E. SIMPSON, Louisville.

I have just returned from Indianapolis where I went to attend the National Conservation Congress representing the Kentucky State Medical Association.

The Congress is doing a work tremendously potent for good and attendance thereto is worth any man's while. A casual perusal of the list of speakers guarantees the highest standard possible, including, as it does, the names of men and women whose work is attracting national attention, while the wide range of subject matter covered offered something of interest to every kind of mind which Conservation in any of its legion of forms and activities appeals. While such meetings always offer an opportunity for the fanatic and zealot, with vigorous but impractical ideas, to exhibit their wares yet so much of good wholesome thought, such radiant reflection in speech of tangible things being done, that even the crank seems endowed with prophetic vision.

I heard a most masterly address by Gov.

Woodrow Wilson yesterday afternoon (I did not hear his address at night which was political) on the Conservation of the Nation's Vital Forces. He is a logical and at the same time a charming speaker. Gov. Hadley spoke this forenoon and his address was well worth hearing. Drs. Wiley, Hurty and Dowling spoke on Tuesday hence I did not hear them. I called on Dr. Hurty at his office yesterday afternoon and had a few minutes talk with him. He is, as you know, quite enthusiastic about his work, though, perhaps, a little impatient of opposition on the part of the people.

I was especially interested in the exhibit of the Indiana State Board of Health. Dr. Hurty apologized to me about its incompleteness, much of their material being, he said, on the Health Car which was out of the city. There was a rather large array of impure foods, particularly those that were sold before the Food and Drugs Act became a law, showing the real contents and sources of stuff from which they were manufactured together with an estimated cost, etc. Patent medicines were on exhibit with analyses, labels showing changes of formulae and others which had been once advertised for one disease, as syphilis for example, and now advertised as a sure cure for tuberculosis. The fly came in for a goodly share of swatting and the baby was not forgotten. The Entomological Bureau of the State had an exhibit of insects and fungi infesting fruit trees and plant life was very interesting and instructive. There was even a "model home" erected on the main floor of the exhibit hall. I thoroughly enjoyed the meeting.

TYPHOID SERUM

I will consider it a favor if you can find space to include in the next number of your journal the following letter that will be self-explanatory.

About six years ago the writer began to use vaccines in the treatment of typhoid fever. Since that time he has thus treated more than one hundred cases and has obtained numerous articles upon the same subject written by physicians in various parts of the world. It seems possible, however, that some may have escaped notice. He also realizes that many of the profession may have treated some cases without reporting them. A paper upon the subject is now in the course of preparation. In this it is earnestly desired to incorporate reports from a large number of cases, good, bad, and otherwise. He accordingly makes the following request to the readers of this JOURNAL:

Will any one who has used vaccines in the treatment of typhoid fever, whether but one case or more, kindly communicate to him that

fact accompanied by name and address of the reporter. If the results have already been reported, a note of the journal in which they appeared will be sufficient. If they have not been reported, a short blank form will be sent to the physician to be filled out. Due credit will be given in the article to each person making a report. If any physician happens to know of other confreres who have any such cases, it will be appreciated if he sends their names, as they may not happen to read this note. It is hoped that by this means a sufficient number of cases may be collected to somewhat definitely settle the now mooted question whether vaccines are or are not of benefit in typhoid fever therapy.

Reports of cases will be accepted at any time in the future but preferably by November or December of the present year.

Kindly communicate with Dr. W. H. Waters, Director of the Department of Pathology and Bacteriology, Evans Institute for Clinical Research, Boston, Mass.

COUNTY SOCIETY REPORTS

Warren—The Warren County Medical Society held a meeting and barbeque at Chalybeate Springs, Tuesday, September 17th, with the following doctors present: W. L. Heizer, Simmons, Wood, Rau, Helm, Blackburn, J. N. McCormack, A. T. McCormack, Posey, Souther, Cook, Martin, Ewing, Grider, Hampton, Drake, Reardon, Stone, Thomas, Hall, Briggs, Rodgers, Richmond, Lewis. Many physicians came in cars with their families to spend the day at this delightful summer resort.

W. W. Richmond had arranged for a hookworm dispensary and more than 200 people attended, many of them bringing specimens for analysis. The doctor also gave a lecture on sanitation and described his work in Edmonson county. Many patients with hookworm infection were present.

A. T. McCormack delivered an address on the "Result of Work for the Eradication of Hookworm."

W. A. Briggs reported a case of pellagra. This case was seen by several physicians who concurred in the diagnosis.

J. N. McCormack discussed this case and spoke of the Pellagra Conference held at Corbin last year, where over 100 cases were exhibited.

A delightful dinner was served by Mr. Proctor, after which all the physicians attended the dispensary.

J. H. Souther moved the Warren County Medical Society request the Fiscal Court to appropriate sufficient money for conducting hookworm dispensary in Warren county.

J. H. Blackburn seconded the motion and was appointed chairman of the committee.

The society then adjourned.

L. H. SOUTH, Secretary.

SYMPOSIUM ON PHYLACOGENS

THE USE OF RHEUMATISM PHYLACOGEN IN CHRONIC RHEUMATISM.

By EDW. B. RICHEY, Louisville.

The danger in the use of a remedy such as this is that because of its unusual results in cases that have resisted other treatment; we are likely to become over zealous in our advocacy of its use. In other words its results in one case may be so unexpected and so efficient that we are tempted to adopt it as a cure-all without carefully trying it out.

I am endeavoring, therefore, in this brief paper to hew to the line and let the chips fall where they will. I shall make no statements that are allowed to be exaggerated by my enthusiasm and in every way shall give this remedy its just tribute for its efficiency and yet its just criticism.

Every remedial agent has its hindrances which, when possible to remove them, can show its full efficiency. Every internist has observed that in certain individuals standard remedies at times fail to bring results. I do not expect, therefore, that rheumatism phylacogen will relieve permanently all cases.

Each case is a law unto itself and may for some unknown reason not be relieved by this treatment but if many be relieved of suffering (and few to whom it is administered are not relieved) it is still worth our while to use it.

I have reported before this distinguished society, at a previous date, my first case in

the use of rheumatism phylacogen, so will mention it only as to subsequent observation and treatment.

The case was that of Mrs. H., age 62, weight 200 lbs. Rheumatism 11 or 12 years, for eighteen months helpless, could not walk nor comb her hair, etc. Suffered pain night and day. Treated with rheumatism phylacogen February, 1912. Three doses given subcutaneously. Six doses given intravenously. Severe reaction in all except last two, when slight reaction was present. Patient went home relieved of pain, walking on crutches, could comb her own hair, turn over in bed, get up and down but was weak, muscles were flabby. Sent her home fifth day after completing treatment. Having given her tone during that time and continued this two weeks.

No subsequent trouble until August 15. Pains, slight, appeared in both knees and in one hand. Gave four doses rheumatism phylacogen, first 5 c.c. subcutaneously, three doses of 10 c.c. subcutaneously and she has had no pain since. Has walked without crutches but little because of fear of falling, but gets around on crutches very well. Walks all over her yard and all about the house without assistance.

My mistakes in this case may have been, in not continuing the treatment longer in the beginning. But because of the weakened condition I prefer to use subsequent treatment to too long continued treatment.

I believe the average constitution will only stand a certain amount of intravenous treatment. Patient is satisfied and why should not I be.

CASE II.

Mrs. G., age 66, weight 170, white. Had pain in hip and groin and swelling of foot and knee on left side. Pain gave her no rest at night for six months, could walk, but with a limp and severe pain in hip, knee and groin.

Had suffered for fifteen years but worse in past eighteen months. This case had been diagnosed hip-joint disease, chronic dislocation, fracture of neck of the femur, rheumatism and sciatica. Had been treated by many physicians, Osteopaths, etc., and had been to most of the springs said to cure rheumatism, with no relief.

She said the Osteopath made the condition worse. Our first efforts were in the direction of a proper diagnosis. Hence Dr. Moren was called upon to see if we had a sciatica or ileo-sacral subluxation. The doctor found nothing wrong in this respect. Next Dr. Bruce took an X-ray picture of the hip-joint and the picture showed a deposit of some kind around the head of the bone about a quarter of an inch thick. This we readily saw was the cause of the grinding and gritting sensation which the patient complained of so much. The blood examination showed uric acid present. The urine was loaded with uric acid and other solids.

All this with a history of rheumatism in childhood brought us to the conclusion that it was a case of chronic articular rheumatism, involving the hip, knee and ankle joints and both elbows slightly.

We undertook treatment in this case with the hope of relief from pain, primarily, not expecting that the hip-joint would be relieved of the, what we believed to be, uric acid deposit and hence the gritting sensation. Neither did we expect to relieve the patient of the limp entirely, but we felt, and so did she, that to be free from pain when at rest so she could sleep at night, would be worth all the effort to be put forth.

She was given three subcutaneous doses of 2, 5 and 10 c.c. each followed by six doses intravenously of 2, 5, 7 1-2, 10, 10, 10 each the first time. She was very much prostrated but seemed free from all pain and anxious to go to her home fifty-five miles away, so we treated her with tonics for five days and she returned home. This treatment was from June 8th to 23rd.

After returning home she walked into the garden and chicken lot and superintended a large house and servants, and entertained considerably and the limb began swelling and became very large. I went to see her, had hot packs applied and gave remedies to promote kidney and bowel action and soon the limb returned to almost normal. She began suffering again with pains, at times, in hip and

knee, and was advised to return for further treatment, which she did August 28th.

Eight doses subcutaneously were given over the involved joints, all 10 c.c. save the first dose, all with marked local reaction but only slight constitutional reaction.

Pain was relieved and patient began walking again with a cane, and without pain, was able to get up and sit down without pain, but suffered slight pain when attempting to place one leg across the other or in that direction. This pain was felt in the groin.

The patient wrote me Wednesday, October 2nd, saying she was in good health save for slight pain in groin at times lasting for a few minutes and some little swelling in the foot of the affected limb. She says she sleeps better at night, eats well, enjoys freedom from pain when quiet but cannot walk much without tiring and having some pain.

CASE III.

Woman 45, weight 120. Rheumatism 10 years. All joints involved. Negative history otherwise. Diagnosis, "chronic articular rheumatism;" treatment, six doses of rheumatism phylacogen subcutaneously over affected joints, with pain after third dose gradually disappearing. Patient then refused to take any more of the phylacogen and the doctor refused to give other treatment and has heard nothing from her since. But it did relieve her pain and enabled her to sleep soundly like a babe, something she had not done for months.

I have written and spoken upon Schafer's modified vaccine or rheumatism phylacogen so much before that I have entirely expressed myself as to its logical place among our most effective therapeutic agents. I have also spoken in detail as to the method of administration; but I desire to state a few conclusions in summing up.

I am convinced that the use of rheumatism phylacogen in chronic articular rheumatism is entirely justifiable, that it will in most cases relieve pain, that it will not reduce to any great degree any uric acid deposit or correct an ankylosis but will cause the system, by ridding it of the infecting organism, to cease the production of such pathology and put it in condition to gradually rid itself of these complications.

I have not used this remedy in acute articular rheumatism, but believe it to be more efficient than in such long standing and difficult cases as I here report.

In acute cases of not too long standing I am inclined to think the subcutaneous method preferable on account of the severe reaction resulting from intravenous injections. I believe that in the above cases that if results are still unsatisfactory in every detail that I

shall advise a still further treatment subcutaneously over the affected parts.

Credit must be given the treatment in these severe cases for the relief of pain even if no other good is accomplished for thereby the patient is made comfortable and can enjoy some of life's happiness.

Time does not permit me to deal with the causative factor (bacillus of Poynten and Payne) in rheumatism and the Schafer theory of getting rid of this and its toxins, but I will expect this to be brought out in the discussion.

I believe that any fair minded man would sanction the use of the phylacogen as a remedial agent in rheumatism could he but see the relief afforded his patient. Facts and experience do not lie and we must admit that phylacogen in rheumatism is the most efficient remedy thus far in the hands of the profession.

As to the future of the cases here reported we can only conjecture. This disease may reassert itself but we do not think so, knowing that that which acts in vaccine therapy as a curative agent also has more or less place as an immunizing force.

THE TREATMENT OF ERYSIPELAS WITH PHYLACOGENS.

By W. A. JENKINS, Louisville.

Erysipelas has a well known streptococcal origin, and a striking group of clinical manifestations and on account of these two facts it has always seemed to me that this disease furnished a very typical example for the observation of its response or behavior to vaccines. I wish this evening then to present for your consideration a series of cases, treated according to the above mentioned method. Our trials were carried out in the Louisville City Hospital where the most careful, rigid and accurate observations were kept on the behavior of each case. All cases were watched and tabulated by graduate internes assisted by a competent corps of nurses. We had about eight or ten cases of facial erysipelas, some of them very ugly ones. In treating this disease we tried the phylacogens alone, and in connection with other remedies. Our experience was very gratifying and we certainly obtained some excellent results. The phylacogens were administered subcutaneously only in these cases, beginning with the small dose, say 2 c.c. giving a second dose in eight hours if the reaction is not too severe. If the reaction was too severe we waited until the next day for making the second injection. In most instances we obtained a marked systemic reaction and a noticeable improvement in the case. In our experience we found that it was best to use common sense measures such

as thorough elimination by the use of calomel and salines, and the use of about 50% ichthyl ointment constantly applied in addition to the phylacogens. When we used the phylacogen alone without any local application, while the condition seemed to respond systemically it would spread locally and we would have a second systemic saturation; consequently we used the phylacogen in connection with the above mentioned plan. Our final conclusions as to the routine plan of treatment were as follows: As soon as the patient was admitted to the hospital he or she, was put to bed; broken doses of calomel, or calomel and podophyllin were given followed by a saline, thus securing a thorough cleansing of the alimentary tract. The diet was light but nutritious and chiefly liquid in character. Fifty per cent. ichthyl ointment in lanoline was applied locally to the affected area and kept up *pro. re. nata*. The phylacogen was given subcutaneously 2 c.c. as the first dose. If the reaction was very severe we waited twenty-four hours and then gave two or five c.c., as the previous reaction seemed to indicate. Usually it was 5 c.c. Then the next twenty-four hours 7 c.c., then 10 c.c.. The dose of 10 c.c. was repeated for a day or so if necessary until immunization, that is, cessation of reaction, took place. This is your signal to stop treatment.

In conclusion allow me to say that I am an advocate of the use of vaccines if they are used intelligently and scientifically. I do not care whether it be Schafer's, autogenous, or stock vaccines that are used, I believe that vaccines and *allied products*, such as the phylacogens, for example, have come to stay. I believe that they are proving to be of undoubted clinical value, they will not take the place of any or all drugs, or, in other words, do away with drugs entirely, but they are undoubtedly a valuable addition to our therapeutic armamentarium. They are yet in their infancy and their future may be even greater than I predict. I am attempting to give a conservative view of this subject as we now understand it. The future of vaccine therapy is certainly a positive and perhaps a brilliant one.

MIXED INFECTION PHYLACOGEN.

By E. S. ALLEN, Louisville.

Primeval man, in all probability, possessed a natural immunity to bacteria. The prime cause of germ life was that of scavenger, taking care of the smaller particles of putrefactive matter not destroyed by smaller animal life. As a result of civilization, man has so lowered his vitality and natural resistance as to become a host for the bacteria.

Environment and diet have developed

racial characteristics and specific feeding grounds. Bacteria have become pathogenic. Except in a few instances where a drug has bacteriolytic properties, we can only deal with this microscopic enemy to animal life by assisting the natural forces of the body in building up an immunity. The immunity is that which prevents the gaining of a foothold of disease organisms in the animal body, or which neutralizes their harmful products when they have gained entrance.

Immunity hinges on the resistance of the human body to the aggressive and virulence of the invading organism. It must be borne in mind that immunity is only relative. For instance, any animal, naturally immune to a certain bacteria, can be made to succumb by reducing its resistance by exposure to cold or by starvation.

We believe that all acute and many chronic diseases are caused by the metabolic products of bacteria, and that our therapy must consist, either in fortifying the body against invasion, or assist in the destruction and neutralization of their products after infection.

Dr. Schafer after using single strains of both autogenous and stock vaccines, and making careful cultural study of the excretions and secretions, was able to demonstrate, day by day, bacteria that could not be found in the fluid on first examination, especially in those cases in which the end results clinically were not good. As a result of repeated experiments, he concluded that the animal economy which normally is the host of microorganisms that are pathologically latent, when the resistive properties of the body are lowered become capable of setting up a disease process.

The chemical forces of the blood are turned toward the primary invading and infecting germ, while the other bacteria appear on the battle field as an unforeseen enemy, and that if we would take for granted that the enemy was lurking in the back ground, waiting for advantage, and prepare the forces of the blood, that they too could be arrested in this invasion and fight.

As a result of an attack of disease or in response to the stimulus of the injection of the organism or its products, we have developed in the body so injected, certain specific antagonistic properties to the organism, which are naturally demonstrable in the blood serum or other body fluids. These we term antibodies, opsonins, bacteriolytic products, etc.

Dr. Schafer's argument is most plausible, though in opposition to all late biological theories. Yet clinical results as given by him and many other experimenters bear him out. It means that we are only learning the alphabet of cell chemistry and need considerable enlightenment on the products of bacterial

growth on artificial culture media. It is a question of more chemistry in the laboratory of the physiologist.

We know that when we inject a bacteria or its products into the animal economy, as a result of the activity of the cells of the animal invaded, antibodies are formed which neutralize the toxins or destroy the bacteria. These antibodies are thrown off free receptors capable of combining with and fixing the toxin radical, rendering it inert to fix itself to the body cell, which, if a sufficient number combine with the resident cell, poison it, and death of the cell results.

There has now been demonstrated a product not only antitoxic but anti-microbial, which is not thrown out to all bacteria. The tetanus, diphtheria and pyocyanus are examples. So if antibodies are developed against bacteria that do not liberate an extracellular toxin, and the antibody is antimicrobial we, by disintegration of these bacteria, liberate a secondary poison which necessitates the development of a second antibody, and it is possible that, for instance, in a colon infection of the peritoneal cavity, where nature destroys millions of bacteria, so liberates a new endotoxin in such enormous quantities that before she reinforces her cellular elements they have received their fatal dose. Is this possible with so powerful an antimicrobial agent?

Dr. Schafer is of the belief that all infections are "mixed infections," that except in rare instances there is no such thing as infection by a single species of microorganism; that while one species may predominate, the pathogenic process engendered by it is accelerated and intensified by the complicating presence of other organisms of other species. In other words, that in the course of an infectious disease the symptoms are due not only to the effects of a single species of organism (the specific infection), but to the influence of other organisms whose pathologic role is not significant, but which must be reckoned with in any successful scheme of therapeutics.

Dr. Schafer further believes that the human subject is at all times the host of a great variety of organisms and harbors these pathogenic bacteria without harm to itself during periods of physiological resistance, at or above par, and in the absence of any solution of tissue continuity. When the resistance is below par, or a solution of continuity of tissue occurs, the bacteria harbored by the human host assumes pathological significance.

Furthermore, he contends that certain diseases, as typhoid fever, pneumonia, tuberculosis, erysipelas, rheumatism, and others, are objective symptomatic manifestations of the preponderance in the patient of the toxic and

destructive products of the peculiar species of organisms to which the etiology of the disease is usually ascribed as bacillus typhosus in typhoid fever, bacillus pneumoniae in pneumonia, the bacillus tuberculosis in tuberculosis, etc.; and, in addition, the symptoms are due in part at least to the destructive action of certain materials produced by complicating organisms which are always present in great variety and number.

As an illustration, attention may be directed to the not commonly accepted idea that in pulmonary tuberculosis the greater danger to the patient, much of the difficulty of the treatment, and many of the most notable symptoms, such as loss of weight, high temperature, disturbance of circulation, purulent expectoration, destruction of tissue, etc., are due to the complicating organisms, and if the so-called "mixed infection" can be checked or eliminated efforts may be directed against the bacillus tuberculosis with far greater success than has heretofore been possible in the treatment of this condition.

When bacteriolytic substances are developed in the body we have two factors to consider: First, a substance similar to antitoxic molecule, but which in itself has no power of injuring its specific bacterium. This is known as the amboceptor, or immune body. It is the specific product of the activity of a specific bacterium against the body cells attacked. In itself it is incapable of injuring the bacterium in response to whose attack it was produced. The second factor in the bacteriolysis of the specific bacterium is something normally present in the serum and which is capable of disintegrating the bacterium, provided it can have access to the bacterium through an intermediary amboceptor. This is called the complement. The complement cannot act upon and destroy an invading bacterium unless the amboceptor is present to make the necessary connection.

This apparently could be left unsaid except that it leads to a question in my mind possible; that of complement deviation or deflection.

Dr. Schafer's method of administering the by-products of bacterial growth is in opposition to our views of the negative phase in the opsonic index following the injection of bacteria or their products. Some unknown metabolic chemistry is taking place. Is it not possible in the rapid injection of large doses of bacterial products to generate some inequality in the complement and amboceptor ratio, and thereby paralyze the resistant forces of the blood?

It has been demonstrated that if there is not sufficient immune body or amboceptor in the body serum containing abundant complement that only a portion of the bacteria pres-

ent will be destroyed; that if we can increase the immune body, all of the bacteria will be destroyed and if we continue to increase the immune body out of proportion to the complement, that the destruction of bacteria ceases—and that the bacteria not destroyed grow unmolested.

For instance, if we have an excess of amboceptors for available receptors on the bacterial cells, only a portion of the amboceptors can attach themselves to their specific bacteria. The free amboceptors not being able to form a union with the bacterial cell receptors combine with the complement present. Unless the complement be in excess, there will be no free complement left to join into the amboceptors attached to the bacterial cells and consequently bacteriolysis does not take place.

This in all probability amounts to nothing, but is a theoretical question that occurred to me.

It is certain that our knowledge of the means by which the economy is able to overcome bacterial invasion is limited.

Various substances, as agglutinins, precipitins, stimulins, lysins, and opsonins are each considered to play a part in assisting the white blood cells to destroy bacteria, while Wright has demonstrated a substance in the blood which acts directly on the bacteria leaving them in a helpless state for phagocytic destruction.

When a cell extracts from the plasma chemical nutrient, radicals and oxygen, and by a metabolic process of chemical combination manufactures a new substance, a secretion having a physiological role in the economy, and by a process of katabolism eliminates the refuse of its work, it has performed its physiological function.

But when the toxic radical or bacteria or product combines with the receptor of the cell, the cell either fails to manufacture the secretion necessary to the function of other structures or turns out a pathological secretion of a toxic nature, and the physiological waste is interrupted.

In the bacterial filtrate offered by Dr. Schafer he is supposed to fortify the cell against bacterial invasion; to cause the cell to manufacture enough extra receptors to not only fix and render inert the bacterial toxine, but to manufacture a substance toxic to the bacteria.

Clinical results seem to prove that he has given to the profession a therapeutic agent in bacterial filtrate, a means of fortifying nature against bacterial invasion or immunizing her in case of infection.

It appears to me that in the surgical field, with a gangrenous appendix with the operative site generally infected, if the bacterial filtrate is used hypodermically or rather in-

travenously, that we could materially hasten wound repair, and that in a beginning peritonitis an intravenous injection would abort the inflammatory process.

We, as a rule, know that we have to deal with only three or four different bacterial strains, and to use a filtrate one-half strength of the suspected germ and equal proportion of the other probable varieties.

I have only used the mixed phylacogen in a very few cases, and all of these were in chronic infections of the bladder. The subcutaneous method was used and marked benefit resulted. From statistics on this subject, I believe that if I had used the intravenous method my results would have been satisfactory. There apparently seems to be no danger as the minimum lethal dose for a man weighing 150 pounds is over 800 c.c. and the dose administered is from 1 to 20 c.c.

DISCUSSION.

Earl R. Miller, (Detroit, Mich.): I wish to assure you that I appreciate very much the privilege of hearing these papers this evening. They have presented the subject of phylacogens in a very fair and conservative manner. This preparation is comparatively new to the profession and deserves due credit for what it proves itself to be clinically. We have conducted a great many experiments for the purpose of determining, if possible, what phylacogens are and the manner in which they exert a beneficial effect. We have thus proven certain theories which are far from conclusive, but the value of any medicinal agent is its value when given in a certain condition. You have heard many conditions cited here to-night and you have heard the results. I have seen a great many doses of phylacogen administered in different conditions. However, I have not had the opportunity of following any of these cases to a final termination. Therefore, I am going to refrain from going into a general discussion of these papers. I am happy to have the privilege of being here this evening and of hearing you gentlemen who have had practical experience with phylacogens, discuss the papers. At the conclusion of the discussion, if any of you have questions that you wish to ask regarding dosage, reaction, or anything in connection with the administration of phylacogen, I will be glad to answer those questions to the best of my ability.

M. L. Ravitch: I admire the house of Parke-Davis for its business-like methods; if physicians as a rule were as business-like as they are, we would all have been better off. It appears that the time is coming when we will all have to go out of business; as soon as a disease is diagnosed, an injection of a serum of one kind or another, will be administered and the patient will be cured. From the symposium I have heard to-night it seems to me that very few clinical cases have

been given as a basis of the symposium. I admire the paper of Dr. Allen in particular; it is a classical one. However, he hardly cited any cases treated with phylacogen and the few he did he did not give any results; he says he does not know but he thinks they were benefited.

I also admire the paper of Dr. Jenkins, who cited a few cases of erysipelas that were apparently cured by the use of phylacogen. However, erysipelas is an easy disease to cure. Dr. Jenkins said that he applied a 50 per cent ichthyol solution, and if we do that and give intestinal antiseptics as calomel, these patients will get well without phylacogen. The truth of the matter is that a great many of us do not know our materia medica; we have not studied it and we do not know physiological chemistry. Ask the average physician what he knows about the chemistry of the tissues, and nine times out of ten he will admit that he knows nothing about it. Many wonderful cures of erysipelas by the use of phylacogens, and thousands of cases of acne have been reported as having been cured by means of vaccine, but when you nail these men down to the real facts very few cures, if any, have been really accomplished. At the last meeting of the American Medical Association, a doctor read a paper before the Section on Dermatology, giving a long history of wonderful cases that were supposedly cured, but when he was nailed down it was all imaginary cases.

Gentlemen, I have come to the conclusion that we are too hasty in using sera, and make too hasty conclusions. Since we don't know the chemistry of the toxins of sera, we must be careful in using them. Let us study our materia medica; let us study the physiology of drugs and their influence on the tissues. I really believe no serum should be used until we know its chemical toxin. Vaccine in acne has proved to be a failure. Much of the disease, except when it is of bacterial origin, is due to some reaction, and until we study the cause of the reaction we cannot come to a definite conclusion. In some diseases that are supposedly of bacterial origin, the bacterial element is secondary.

Harry J. Phillips: Dr. Ravitch is perhaps right in some respects. However, you will all recall that a great many doctors were skeptical as to the value of anti-toxin in diphtheria at first, but to-day practically every physician uses it; or, in the few instances where it is not used, we feel that the physician is not quite up-to-date to say the least. As I understand it, phylacogens are along the line of mixed infection vaccines, and this principle has been supported by a large clinical experience, augmented by the experience of Dr. Schafer himself. From the results obtained from this form of treatment there have been deduced these facts: (1) that all acute diseases and nearly all chronic diseases are caused by the metabolic products of bacteria; (2) that the human body is normally the receptacle, or

host, of a great variety of organisms, pathologically latent, but which, under certain conditions, become capable of producing disease, and (3) that the growth of these organisms may be influenced by metabolic products of bacteria grown in artificial media.

The theory has been advanced that there is no such thing as an infection due to a single organism, but that it is due to the action of a great many organisms. "Phylacogen" is a term derived from two Greek words, and translated literally means a "phylaxin producer". Phylaxin is a term that is used to indicate the antibodies found in animals that have acquired an artificial immunity against a given disease. Phylacogen is not a bacterial vaccine in the sense that the latter term is generally understood. Phylacogens are sterilized aqueous solutions of metabolic substances derived from bacteria grown in artificial culture media.

Phylacogens are made from a great many varieties of bacteria—the staphylococcus and streptococcus pyogenes, bacillus typhosis, bacillus coli communis, etc., etc.

Personally I have had experience with two varieties of phylacogen—the mixed infection and the rheumatism phylacogens. I used the former in a case of Pott's disease, one of the most severe cases I have ever seen. This case, however, was not a fair criterion of the value of the phylacogen, because it was a terminal case, and absolutely incurable. This man had necrosis of the vertebra with the formation of considerable pus which found its way along the psoas muscle and opened in the groin. He was having chills and septic sweats, with a high range of temperature. I gave him nine or ten injections of the mixed infection phylacogen, beginning with 5 c.c. and rapidly increasing the dose to 10 c.c. While, of course, this remedy could not cure the man, I am sure that it greatly benefited his condition: he slept better, his temperature remained almost normal, the sweating disappeared, and he was improved in many respects.

The other case was one of rheumatism in an old lady, about 58 years of age, who is, one might say, prematurely aged. She appears to be nearer 78 than 58, judging from her general appearance, heart and arteries. For more than four years she had not been able to get about her room except with the aid of crutches and a cane. Her trouble is chronic articular rheumatism. I began the use of rheumatism phylacogen, giving her an initial dose of 5 c.c. and rapidly increasing it to 10 c.c. The reaction in her case was marked, and I want to say, gentlemen, I have found, in the few cases I have treated, that the more pronounced the reaction, the more decided was the patient's improvement. She had a rise in temperature of three degrees, her pulse was accelerated, and there was considerable prostration attended by profuse sweats, but by the next day she had begun to improve. The pain was not so severe, her

appetite was better, and she showed improvement generally. As the administration of phylacogen was continued, she continued to show improvement. I gave her some fourteen injections, being compelled twice during this period to temporarily discontinue the treatment because of the severe reaction. I think I can say, conscientiously, that if she were twenty years younger and had more determination and will-power, she would be able to get around without the aid of a cane. She gets about the house and into the yard with the help of a cane.

I cite the above cases because of the fact that they came under my personal observation.

I believe there is a future for phylacogens. There are two ways of administration—subcutaneously and intravenously. I have given it both ways. I gave it intravenously by error. I intended at all times to give it subcutaneously, but on one occasion in the effort to do so I accidentally hit a vein. The reaction was most marked and severe in this instance. Possibly the only adverse comment that I could make is that in administering phylacogen intravenously, we should be careful to know the condition of the patient beforehand. We should be on the lookout for arteriosclerosis and various forms of heart lesions, as well as nephritis, because after an intravenous injection the reaction is very marked and depression is great, the patient sometimes becoming purplish with blue lips, with rapid shallow respiration and in a state of collapse, which is apt to frighten the physician as well as the family very much. If given subcutaneously, there is no contraindication to the use of phylacogen, with the possible exception of nephritis. I always begin with 5 c.c. and increase the dose up to where I think the patient is perfectly safe. I would not hesitate to use this remedy in the future in any case that I think needs it.

C. G. Forsee: I have had experience with phylacogen treatment in two cases. One of these was a young man, about 24 years of age, with an arthritis and almost complete ankylosis of the arm, being able to move it only about five degrees. He came here from Illinois for relief from the pain. He said he did not care so much about the function of the arm as he did to get rid of the intense pain. I began with 10 c.c. subcutaneously—a rather larger dose than is usual. This was followed by a reaction with a temperature of 104.1-2. I had him in the infirmary where he could be watched. After this reaction had subsided he developed a very marked urethritis. He had no discharge when he came into the infirmary. I gave this man ten injections, the last dose being 20 c.c., all subcutaneously. After the first dose the fever reaction was comparatively mild. He was comparatively free from pain after the initial administration and remained so until about a month ago, when I received a letter from him saying that the pain had returned, and de-

siring to know if some one in his town could not give him the same form of treatment.

Another case was in a man whose age I do not know, but he was old enough to be a grandfather. He gave a history of gonorrhea contracted five years ago, for which he had undergone treatment in Cincinnati for a period of five months. He thought he was cured of the gonorrhea and came to me for treatment for rheumatism. I began the use of phylacogen, giving him a ten c.c. dose, which was followed by a chill and fever reaction. I gave him a dose of 10 c.c. every day until the last, when I gave him 20 c.c. A good deal of pain attended these injections. It requires some little nerve on the part of the patient to stand for putting 10 c.c. of medicine under his skin every day, but this man had nerve, and said go ahead and I did.

The most striking feature about these cases was the fact that in each case the patient developed a urethritis, and each of them had a return of the gonorrhea. The older man had no appetite, had lost some weight, and thought he was going into a decline.

Another very striking feature about both of these cases was the marked sweating. Both of them sweated a great deal, and there was an increased flow of urine in both cases, more marked in the older man. I did not measure the quantity, but he told me that it was far above the normal amount of urine. The older man left for a six-weeks trip on the road immediately after receiving the treatment, and when he came to see me again he had gained 14 pounds. He said he had never eaten heartier in his life than he did while on this trip, and he was entirely free from pain. While he said that the treatment was about as severe as could be administered, he was very much pleased with the results, and I was also.

Herbert Bronner: Some time ago when Dr. Larned came to this city in connection with phylacogens (although I do not think they had been given that name at that time), I asked him what was the content of this remedy, and he frankly told me that neither he nor Dr. Schafer knew. On purely theoretical grounds, I objected to using a remedy the composition of which I did not know. However, I did use it in some experimental work at the City Hospital although, as stated, at that time it was not known just what phylacogens were, and the manufacturers were, therefore, unable to standardize the remedy. I would like for Dr. Miller to tell us whether it has since been ascertained just what phylacogens are, and whether any attempt has been made to standardize the remedy.

Irvin Abell: Most of those who have discussed this subject have confined their remarks to the use of phylacogens in purely medical conditions. I would like to add a report of three cases of surgical conditions in which phylacogens were used.

The first was a case of tuberculous peritonitis,

with a temperature of 103, and pulse 120, upon whom abdominal section was done, the fluid evacuated from the cavity and the wound closed. Subsequently the patient was given a mixed infection phylacogen until the fever disappeared, followed by the administration of tuberculosis phylacogen, or vaccine as it was called at that time. The patient made a complete recovery with a gain in weight of 25 pounds in the course of six weeks and returned to work without temperature. In the course of two months I have had no further report from him. So far as the effect of the phylacogen is concerned, this case may possibly be disregarded, inasmuch as the ordinary routine surgical measures were carried out.

In each of the other two cases, if the result obtained was not due to the use of phylacogen, it was, to say the least, a very happy coincidence. One of these was a man who had a cystitis apparently without cause. By this I mean that the condition was not of tuberculous origin, since Dr. Allen was kind enough to examine the urine carefully and repeatedly in search of tubercle bacilli, with a negative result. This patient had an ascending infection from the bladder, involving the pelves of both kidneys. An abscess developed in the left kidney, which was opened and drained. Examination of the urine showed colon bacilli, staphylococci, streptococci, and other bacteria which I do not now remember. He was placed upon the mixed vaccine of Schafer and under this treatment alone he made a perfect recovery. The urine became free from pus, the fever disappeared, and he returned to work as the proprietor of a grocery.

The third case is still more striking. I had in the Infirmary at the same time two parotid infections following operation. One had a ruptured appendix with general peritonitis. In this case the Schafer vaccine was not used and the case went on to suppuration with a temperature of 103. Suspension of the uterus was made with no infection, the wound healing by first intention. On the second day following the operation the patient developed a temperature of 103, with marked swelling of parotid extending up to the eye, which was partially closed, and down the neck as far as the clavicle. This patient was given no treatment other than three doses of Schafer vaccine. Following the first dose the pain subsided; after the second dose the swelling subsided, and 36 hours following the third dose all the oedema had disappeared, leaving a very slight enlargement of the parotid which gradually subsided without further treatment.

In closing, I would like to commend Dr. Ravitch to a more careful study of Dr. Allen's paper, since he dealt purely and simply with the physiological and pathological chemistry of the cells.

J. A. O. Brennan: While it is true that we do not know much about phylacogens, still I believe that if they do not do any more than relieve the

pain, their administration is worth while. The results I obtained recently in two cases of epididymo-orchitis were perfectly marvelous. One of these was a man who came to my office with a most horrible condition, accompanied by terrific pain. I gave him ten c.c. of phylacogen and sent him home.

When he came back to my office the next day while the swelling was still very bad, it was not quite so marked as on the previous day and the pain had disappeared. Even pressure would elicit but very little pain. The same was true in the other case, so I believe that if we do nothing else in these cases by the use of phylacogen except to relieve the pain, we have accomplished a whole lot.

J. Rowan Morrison: As has been stated, this subject is still in its infancy. I have been very skeptical, but I have prayed for faith and I think I am gaining some little faith, gradually. I have investigated the subject, having gone very thoroughly over the literature pertaining to it in the Transactions of the Congress of Physicians and Surgeons two years ago, and the opinions expressed at this Congress certainly did vary. Some men got results and some did not. One thing that has impressed me in talking to men who ought to know something about it, is that the men who are skilled in the science of bacteriology do not, as a rule, place so much credence in the benefits to be derived from the various forms of vaccines, as do the men who do not understand bacteriology and serology thoroughly. That the phylacogens, or vaccines, accomplish a great deal of good in many instances, there is no question. In chronic infections, where the condition has become wall-off, such as chronic gonorrhea, for example, there is no doubt that the administration of vaccines does a great deal of good, but in acute infections, where there is plenty of free material to create all the antibodies that are necessary, why should it be necessary to inject something to increase the production of antibodies?

There are a lot of different theories about the action of vaccines, but they all come back to Ehrlich's side-chain theory which, while no one has been able to disprove it, is only an assumption, and makes a nice hypothesis to work upon.

Virgil E. Simpson: I too, perhaps, have been doing more praying along this line than in most other lines in which I have engaged. I have used these agents in several cases at the earnest solicitation of the local representative of the firm that manufactures it. In one case of tuberculosis in which I administered eight doses, the patient died within four weeks after the administration was discontinued. In justice to the agent, however, it should be said that this case was practically hopeless when treatment was begun. I used it in another case of tuberculosis in which seven doses were administered with no improvement in the lung condition that was discernible upon physical examination.

I have used the agent in only one case of rheumatism, in which there was a mitral regurgitation, with absolutely no improvement. I have used it in two cases of erysipelas. One case (which is the only one I will refer to) was of the facial type, and was one of the worst cases that has ever come under my observation. Both the upper and lower eye-lids were involved, the oedema being so extensive that the eye was completely closed. Necrosis occurred, with considerable sloughing of both the upper and lower lids. In this case no treatment other than the phylacogen was used, and the result was—to be modest—satisfactory. The temperature subsided promptly and the local manifestations disappeared much more quickly than in any case of erysipelas I have observed. I administered the agent intramuscularly (which I believe is preferable to subcutaneous injection), in the abdomen in each case.

The patient I referred to was a man, 55 years of age, who, as I learned after having been in attendance upon him for twenty-four hours, was a morphine habitue. His wife stated that he had been using morphine for twenty years to her knowledge, and she could not say how much longer. He was in very poor physical condition, but despite these facts, the result was, as I stated, satisfactory. On the eighth day following his recovery from the erysipelatos condition, so far as the local condition was concerned, he had a recurrence, beginning on the left arm. If I had used the vaccine intramuscularly or subcutaneously in that locality, I would have been disposed to doubt my own technique. However, as stated, the injections had been made in the abdomen, while the recurrence began in the left arm. Within eight hours the nose became involved, and in four hours more the right eye became involved, with marked oedema. The right shoulder over the deltoid also became infected. I began the administration of phylacogen as soon as I was called, which was within six hours after he had noticed the first manifestations of the recurrence. He was given full doses at eight hour intervals, with absolutely no response, and his recovery from the recurrence was that which is characteristic of most cases of erysipelas—comparatively slow.

My conclusions in that case were, that while the response in the first attack was truly gratifying, the agent did not seem to increase the patient's powers of resistance sufficiently to prevent a recurrence, and that the administration of the agent in the second attack was apparently of no value whatever.

F. T. Fort: I do not believe I can add anything to what has been said; in fact, I believe I know more about phylacogens now than I did when I came here to-night. I had not been very favorably impressed with phylacogens, probably because I had given them little or no study. I used the anti-streptococcal serum in a number of cases several years ago, and did not get results,

so I went back to whiskey and strychnin and continued to get results from that. I used phylacogen in two or three cases of chronic acne last year, and I believe I got good results. Knowing the men who have reported cases here to-night as well as I do, if I have any cases in the future in which I believe phylacogens are indicated, I will not hesitate to use them.

E. S. Allen: I believe that, in the use of vaccines or phylacogens, the end results depend very largely upon a correct diagnosis of the condition present. Demonstrate the causative agent and give phylacogen accordingly, allowing the greater proportion of the filtrate to be from the bacteria that is the causative factor.

I do not think there is any doubt that we get marked results from the administration of this bacterial filtrate, although just what the chemical nature of this by-product, or excretory product, of the culture media is, has not yet been demonstrated.

Dr. Morrison stated that he could hardly see how vaccines could do much good in acute infections, where one would think the bacteria already present would stimulate the production of antibodies sufficiently to bring about immunity, but we must take into consideration that in an acute infection, where virulent bacteria are present in great numbers, we must have enough bacteria destroyed to stimulate nature to resistance, and that when we inject dead bacteria, the cells are made to deal with the endotoxin of the bacteria and nature is stimulated by artificial means, where previously too few bacteria were killed to accomplish this result.

I would like to relate a little coincidence in a case in which I used rheumatism phylacogen with very gratifying results. The patient was a married woman whose youngest child was twenty-two years of age. About two years after the birth of this child she was operated upon for extrauterine pregnancy, the tube and ovary on that side being removed. She had not been pregnant since that time. Two months after the administration of phylacogen she became pregnant, and last week was delivered of a healthy baby.

Edw. B. Richey: I have enjoyed the discussion very much. I agree with one of the gentlemen who made the statement that the number of cases that has been treated with phylacogens in this city is too small to be regarded as positive proof of the efficiency of this remedy, but when we take into consideration the statistics of *mca* from all over the country, we find that the balance is in favor of phylacogens as a very good remedial agent. Therefore, it seems to me that we are justified in proceeding further in our efforts to find out just what the agent is, and if it is found to relieve certain conditions which we are unable to relieve by other means, then we are certainly justified in using it. I think we are sometimes ultra-conservative with respect to new remedial agents, often with detriment to our-

selves and our patients. So far as a knowledge of the exact composition of a remedy is concerned, I think the greatest consideration is whether or not we get results from it. If we can relieve pain and satisfy our patient, it seems to me that is one of the most important points to consider.

Earl R. Miller, (Detroit, Mich.): Dr. Bronner has asked a very hard question. When we first began to work with phylacogens, we also endeavored, by experimental work on animals, as well as by all other known methods, to determine how phylacogens produced the beneficial results which follow their proper administration. We have had a number of trained bacteriologists and research men at work upon the problem continually, but so far we have been unable to determine what the exact mode of action is. It is presumed by a number of observers that phylacogens may contain a metabolic product entirely different from any of those which have formerly been recognized; that in the early growth of bacteria there is a substance discharged or excreted that we do not get in a growth of greater age; that is to say, during the early growth of bacteria a substance is excreted that is not found in the filtrate after a culture has been allowed to grow a greater length of time. It is possibly true that this same substance is found in bacteria from which bacterial vaccines may be in an embryonic stage or form, perhaps not completely developed chemically, and that after the normal functions of the bacteria has been completed by excreting this substance it may prove to be a different form to that which we find it in the cell (bacterium).

Phylacogens are standardized by having the various organisms used in their preparation present in the material before filtrating in approximately equal proportions.

Hugh N. Leavell: I would like to ask Dr. Miller if there are any contraindications to the use of phylacogens, and, if so, what they are?

Earl R. Miller: We do not recognize any condition as a distinct contraindication to the use of phylacogens. However, we warn physicians against the use of phylacogens in terminal cases, where the thread of life is very slender, and where the shock from even a subcutaneous injection of normal salt solution, or possibly the puncture by the needle, may cause a fatal termination. While we do not recognize arteriosclerosis or a condition of extreme anemia as being distinct contraindications to the use of subcutaneous phylacogens, still we give them the benefit of the doubt and advise that such patients be not injected with phylacogens. We have had a great many reports of death from the administration of antitoxin; for instance, that a patient was injected with a certain dose of antitoxin and in so many minutes he was dead. We have no positive evidence that the administration of the agent was the actual cause of death of that individual. I remember very well a man telling me of his early experience with diphtheritic antitoxin. He said

he was called in consultation in a case in which there was some question as to whether antitoxin should be used. He recommended that it be given while the man with whom he was in consultation objected to its administration, and while they were arguing the question the little patient arose from the couch on which he was lying and started towards the open door for air. He stood at the door with his hand on the knob for a moment and then dropped dead. Now, if they had administered antitoxin five minutes previous to this fatal termination, the family, the physician and all concerned would have been certain that the antitoxin had caused the death of the patient. We have had a few cases in which death has occurred following the administration of one or more doses of phylacogens. In most of those cases post-mortems were held and in every instance it was found that death had been caused by other conditions present and not by the administration of phylacogen. In two cases death was due to a malignant heart, and competent men who performed the post-mortems testified that death could in no way be attributed to the administration of phylacogen.

There is a tendency among some of our medical men to be alarmed by the reaction. We have learned to disregard the reaction entirely. I was in Kansas City during a meningitis epidemic there a few months ago, and witnessed the administration of phylacogen to patients who were suffering from chronic meningitis, in which there was a rise in the temperature to 107, with a pulse that could not be counted, and yet those patients, within six hours, returned to their former range of temperature, 100 to 101, with a pulse of from 110 to 120. The dose was repeated the next day with a similar reaction, and yet the quality of the pulse returned to the same volume, which convinced every one that the administration did not in any way effect the volume nor quality of that pulse.

We have something like 2,800 case reports filed in our department at Detroit, which represent a good many thousand injections, and after a close study of these cases we have failed to observe a single case in which it can be definitely stated that the injection injured the patient in any way. In every case the patient recovered entirely within a very short time and the administration did not affect adversely the usual heart complications that we find in connection with rheumatism; in fact, a number of men to whom I have talked claim that the cardiac symptoms rapidly disappear after removing the source of the infection—the rheumatic condition.

F. C. Askenstedt: I would like to ask Dr. Miller whether any attempt has been made to produce phylacogens from the bacteria from which antitoxins are made, such as the diphtheria bacillus, or the tetanus bacillus?

Earl R. Miller: Yes, sir. Dr. Schafer claims to have treated a few cases of diphtheria with

phylacogen, with somewhat more prompt results than are usually observed following the administration of antitoxin. We have conducted no experiments ourselves. Our conclusions are based absolutely upon the experience of men who have tested these agents independently of Dr. Schafer. Not that we disregard the experience of Dr. Schafer, but in order that the character of our case reports may be absolutely above reproach the experiments have been conducted by men of heavy hospital and general practice. The reason we have not carried out clinical experiments with a diphtheria phylacogen is that we do not feel that any physician would be justified at this time in administering a phylacogen when he has an efficient agent in the antitoxin. In the present day a man is almost criminally negligent if he does not administer antitoxin immediately upon making a diagnosis of diphtheria, and I will ask whether any of you would feel justified in experimenting with phylacogen or any other agent, after making a diagnosis of diphtheria, when you have an efficient specific at hand? For this reason I think we would have considerable difficulty in making a clinical test of a diphtheria phylacogen.

V. E. Simpson: Where do you get the bacteria for the manufacture of phylacogens?

Earl R. Miller: During the past eighteen months we have had cultures from practically every large medical center in the country. These cultures are first grown separately and then collectively, in order that the phylacogen may contain as many varieties as possible.

Edward Speidel: Which method of administration, subcutaneous or intramuscularly, is the preferable one?

Earl R. Miller: The subcutaneous is the simpler method and the one which seems to have been used by the greater number of physicians up to the present time, although we find a certain number of cases that will not respond to the subcutaneous injection that will respond to the intravenous administration. Our attention has been directed to this in a number of instances. In one case of gonorrheal arthritis, the patient was given a number of doses of gonorrheal phylacogen, the dose being increased from 5 to 10, 15, and even 20 c.c. with little or no benefit. The patient was then started on small doses intravenously, with marked reaction and prompt improvement after the first dose. We now find that a number of men who have been using phylacogens for more than a year, during the first few months gave it subcutaneously but are now using the intravenous method exclusively.

Some cases will have a more marked local reaction than others. Why this is we do not know. Some patients are peculiarly sensitive and manifest considerable local reaction to any injection. I think it is safe to say that in such patients small intravenous injections are to be recommended.

Intravenous injection should be started with a very small dose (not over $\frac{1}{2}$ c.c.), gradually increasing it until a dose of 5 or 6 c.c. is reached. We think that it is seldom necessary to give more than 5 or 6 c.c. in the vein. You will find some cases in which, when administered subcutaneously, the phylacogen will not produce the desired result, presumably because not sufficient phylacogen gets into the circulation at one time to produce the effect. In such cases intravenous injection will usually secure prompt results.

J. W. Heim: Do you get better results in those cases in which the reaction is most marked?

Earl R. Miller: Not always. Early in our experience with phylacogens it was thought that the degree of improvement was in direct proportion to the amount of reaction that followed each dose, but we have found that this is not always true. Frequently the patient will show marked improvement from the very first dose, with a mild reaction after each injection. Again, some cases will have violent reactions and yet improve slowly. Some cases that require fifteen or twenty injections, and finally recover, will have a most violent reaction following each dose.

When to stop the treatment is a question of considerable importance. Some patients are apparently symptomatically cured after four or five doses, and yet if the treatment be stopped they will suffer a relapse. Some of these patients will not have a relapse, but a certain percentage of them will, which means that those patients should have had more phylacogen. Ordinarily, if they do have a relapse, a few additional doses will relieve them entirely. Just when to stop the injections is a question we have not been able to decide. It will be largely a matter for the good judgment of the physician, based upon the general condition of his patient, and even if the patient is apparently symptomatically cured, and then relapses, the indication is to at once resume the treatment and continue it until all the symptoms of the condition have disappeared.

CLINICAL CASES.

NEOSALVARSAN.

(WITH REPORT OF CASES.)

By GEO. H. DAY, Louisville.

Neosalvarsan is a true derivative of salvarsan. According to Ehrlich, it is a condensation product of formaldehyde, sulphoxylate of sodium and salvarsan. The peculiarity of this salt is the paring with the chlora-hydrates of various bases, which was already known. Ehrlich noted years ago that in his chemical investigations of formaldehyde sulphoxylate readily soluble products were formed. As salvarsan contains two amido groups, one or two residues of the salt may appear, according to the method pursued in

the experiment. Neosalvarsan represents the mono product.

About a year ago he resumed these studies, his object being to produce a readily soluble and neutral reacting derivative of salvarsan. His attention was called to formaldehyde sulphoxylate because this combination stops the auto-oxidation of alkaline salvarsan solution for a certain period of time. To that end Ehrlich studied more closely the relation of sulphoxylate to salvarsan, and found that by combining these, a readily soluble neutral solution could be obtained, which, in the animal experimentation, exerted a considerably more powerful action than did salvarsan by itself. In short, neosalvarsan is a derivative of salvarsan, obtained by the action of formaldehyde sulphoxylate on dioxidiamidoarsenolensene.

Ehrlich's idea in attempting to get a neutral solution was to avoid the series of grave reactions sometimes resulting from the strong alkaline salvarsan solution. The fact that in the use of neosalvarsan sodium hydroxide is unnecessary, is an advantage that cannot be overestimated, for the fact remains that caustic soda of the shops was to blame for most of the imperfections noted by surgeons in the preparation of salvarsan, as only a small percentage of caustic soda is really caustic soda C. P. This drug is badly adulterated, and many times we have found that potash, lye, ammonia, and even methylalcohol are substituted for caustic soda. His object at all times was to get a product that, with the simple addition of sterile distilled water, would give a neutral reaction and therapeutically the good results of salvarsan. To this end neosalvarsan was born.

The preparation of the new solution, unlike the complicated method which the preparation of salvarsan demands, proved to be extraordinarily simple. The dry powder is so readily soluble in water that to effect its complete solution, all that is necessary is to sprinkle the amount that is required on the surface of the water. It then requires very little shaking, to say nothing of the mechanical devices, in order to produce a perfectly clear solution ready for use.

Ehrlich advised the solution to be given intramuscularly, and the first several thousand injections were given that way. In Schreiber's Clinic, where most of the experiments were carried out, they were administered in this manner. Some pain was noticed following the injections; and from the pain, the resulting reactions in comparison with salvarsan were nil. Then the intravenous injections were given for the next several hundred cases, the object being, of course, to ascertain which method was best and from which we could expect the best results.

In my experiments with neosalvarsan I have used salvarsan intravenously, and on the whole my results with it were uniformly good. With salvarsan at times the reaction at the site of the injection was very severe, due, of course, to the strong alkaline solution. At times we would also have dizziness, nausea, vomiting, pain in stomach and bowel, which made the employment of salvarsan a major operation, and the necessity of confining the patient for twenty-four or forty-eight hours to the hospital or to a hotel with a trained nurse in attendance.

The size of the dose to be selected, the number of injections to be given, and the length of the intervals between the injections, of course depends entirely upon the state of the disease, the constitution, sex and age, of the patient. As a rule, however, the quantity of neosalvarsan to be used may correspond to the dose of salvarsan which one would use in the same circumstance. The average single dose of neosalvarsan are, for men 0.6-0.9 grams; for women 0.45-0.75 grams; and for children according to the age, from 0.15-0.3 grams. The ampoules are marketed in six sizes, numbered Dose 1 to Dose 6, containing in Dose 1 0.15 grams to Dose 6 containing 0.9 grams. It must be borne in mind, according to its chemical composition, neosalvarsan contains only 66% salvarsan; hence the calculation should always be on the basis of salvarsan when the amount of neosalvarsan is being reckoned. For instance, 1.5 grams neosalvarsan is equal to 1.0 gram salvarsan, and so on. With the idea in mind that large doses were better than small doses, it was the custom of Schreiber's Clinic to inject four doses of 1.5 grams each serially on alternating days, provided the patient was strong enough. Even with these very large doses no serious complications were noticed aside from the frequent medicinal rashes. Since the original experiments, however, it has been shown that treatment should be carried out with smaller doses. Ehrlich now recommends 0.6 grams to 0.75 for men and 0.45 grams to 0.6 grams for women.

Owing to the fact that Ehrlich advised neosalvarsan to be given intramuscularly, and to the fact that painless intramuscular injections could be given in routine office practice, I selected this method for my experiments. As neosalvarsan rapidly dissolves in distilled water and gives a perfectly neutral reaction, as neosalvarsan is better tolerated and can therefore be employed in larger doses, as neosalvarsan's efficiency is at least equal to that of salvarsan, as neosalvarsan is perfectly suitable for intramuscular injections, I selected a series of nine cases for the experiment.

My technique for the injection was to dis-

solve the neosalvarsan in 8 c.c. of cold sterile freshly distilled water. Using a Luer glass syringe and a 1 1-3 inch needle, I injected deeply into the buttocks, two on each side, or four injections of 2 c.c. each, all very deeply into the muscles, the site being the one usually selected in the mercurial injections.

For the intramuscular injection of neosalvarsan, Ehrlich advises using a solution approximately 5% or 0.15 grams neosalvarsan to 3 c.c. distilled water. He also advises injecting beforehand 5c.c. of a 1/2% novocain solution to diminish sensibility. In none of my cases did I use a local anesthetic, and some of the pain naturally resulting would be from its absence. I desired to see exactly the amount of pain caused by the neosalvarsan without a local anesthetic.

CASE I.

Mr. N.; age 40; infected fifteen years ago; intermittent and inefficient treatment, indefinite primary symptoms; denies secondaries; Wasserman positive; first seen eight years ago; one year treatment; protiodide and salicylate injections; refused further treatment; three years ago ptosis right lid; aphasia; no alcoholic history; examination revealed chronic bursitis with infusion, right elbow, right knee; treated for one year; refused further treatment; salicylate injections and iodides; three months ago was seen again; ptosis almost complete, together with a number of cerebral symptoms; reflexes almost absent; again put on salicylate injections and kalium iodide, thirty drops t. i. d. and neosalvarsan given; salicylates every sixth day to tolerance; September 28 neosalvarsan given 0.9 grams, giving two injections each side of the buttocks, or four injections in all, each 2 c.c.; complained of no pain following injection except heaviness in the region, which continued for one hour; on September 30 complained of complete deafness in the right ear, which passed away in three days; respiration, temperature, pulse, continuing normal throughout; no other reaction noted.

CASE II.

Mr. W.; age 29; infected fifteen years ago; primaries and secondaries indefinite; irregular treatment two years by country physician; first seen one year ago; regular treatment for nine months; Wasserman positive; salicylate injections and iodide; was lost sight of for three months on account of changing positions and being out of the city, during which time he was without treatment; physical examination at this time revealed emaciated man, medium height, very nervous, can't sleep at night; head and chest negative; aside from severe nocturnal headaches his condition was altogether satisfactory; advised neosalvarsan

and on September 30 given 0.9 grams, following the regular technique of four injections. This was immediately followed by great pain, which continued for one-half hour before the patient could leave my office; at one time I thought I would be compelled to control his pain with morphia. This pain, he reported later, continued throughout three days; other reactions negative; temperature, pulse, respiration, normal; no rash.

CASE III.

Mrs. S.; married; age 34; infected by husband six months ago; neurasthenic; mouth and throat mass of ulcers; secondary eruption; faded; had salicylate injections, which were badly tolerated; June 17 salvarsan given intravenously, followed by terrific reaction, pain in the arm, dizziness, diarrhea, and pain in bowel which continued for some seven or eight days; small doses salicylates continued weekly, and September 18 neosalvarsan given without local anesthetic; she complained of no pain following injection at any time; temperature, pulse, respiration, normal; local examination negative.

CASE IV.

Mr. D.; age 19; infected June, 1912; typical initial lesion; seen July 18, 1912; secondaries appeared promptly; treponema pallidum demonstrated; Wasserman positive; salvarsan intravenously August 16; very slight reaction; no pain at site of injection; weekly injections of salicylates; neosalvarsan 0.6 grams September 16; slight pain, which continued for two hours; no other symptoms; temperature, pulse, respiration, normal; local examination at present negative.

CASE V.

T. J.; age 22; white; infected one and a half years ago; denies secondaries, except slight eruption on limbs two or three months later and mucous patches in the mouth; treatment begun two weeks after lesion appeared; protiodides; also inunctions; continued this treatment one and one-half months, then changed doctors and received injections of salicylates, having in all four injections; then came to City Hospital two weeks later; examination revealed two enormous condyloma 4 inches long, 2 inches wide, on each buttocks; ten smaller ulcers distributed over the body; neosalvarsan given September 20; complained of some pain following the injection, which lasted for ten hours, after which was very comfortable; temperature, pulse, respiration, normal throughout; discharged four days later or September 24; ulcers and condyloma completely healed; refused further treatment.

CASE VI.

A. S.; female; colored; age 20; infected January, 1911; positive primary and secondaries; treated City Hospital during the month of May with salicylate injections; greatly improved but refused further treatment; left hospital in June; readmitted June 26, 1912. This patient was greatly emaciated; in fact, so much so was confined to bed; she had lost some 60 pounds in weight; very nervous, with a history of using morphine over an extended period; she suffered apparently at all times; had a great deal of pain; she could not be moved by the nurse without great pain, for which it was difficult to account; she had a severe and constant diarrhea, extending over some months; enormous condyloma; vulva and rectum; together with her emaciated condition, made the prognosis rather grave. Neosalvarsan given 0.2 grams September 17; temperature in four hours 101, pulse 110, respiration 24; complained of pain on the left side, cold feet, pain in the abdomen; following day temperature pulse and respiration, normal; September 27, 0.3 grams neosalvarsan given followed by normal temperature, pulse, and respiration; no pain; on October 4 neosalvarsan given .03 grams, followed by normal temperature, pulse, and respiration; she complained of limbs being cold, very little pain; her condition as a whole quite satisfactory; on account of her general condition, don't hope for much; diarrhea has shown very little response to treatment; general condition very little improved; says she feels a great deal better; condyloma practically all disappeared. In spite of her hyper-sensitive condition, neosalvarsan was borne by this patient remarkably well; suffering very little, if any, pain, no change in the temperature, pulse, or respiration, after the first injection.

CASE VII.

M. R.; female; age 23; white; admitted September 13, 1912; noticed eruption on body last May; received internal treatment for syphilis then; physical examination disclosed general adenitis; mouth and throat badly ulcerated; numerous condyloma vagina and rectum; September 16, intravenous injection salvarsan followed by slight reaction with quite severe pain in the back, legs, and arms, which continued for three days; September 27, neosalvarsan 0.6 grams given intramuscularly, followed by quite severe pain in the back and legs, which continued five hours; temperature, pulse, respiration, normal; October 4, neosalvarsan repeated 0.6 grams; three hours after injection, temperature 100, pulse 108, respiration 22; complains entire body aching; severe pains in the back; restless, and chilly sensations, which continue for

twelve hours; her physical condition now is negative; physical examination reveals that the condyloma had disappeared, and the patient is very gratified with her condition.

CASE VIII.

S. B.; white; female; age 55; family and personal history indefinite; no history of lues; doesn't remember primary or secondary lesions; admitted February 11, 1912; two months before admittance noticed ulcer on the gum, which spread until ulcer covered roof of mouth; complained of pain in eating, loss of flesh; previous treatment had been local; so far as could be learned, she had had no previous mercurial treatment. Examination disclosed deep ulcerating gumma of the hard palate; bones not necrosed; no perforation; glands generally enlarged; very tender and ulcerated; pupils negative; reflexes negative; September 27, neosalvarsan 0.9 grams injected, followed by quite severe pain in lower limbs, restlessness, which continued eight hours. Complained severely of the localized pains in the ulcer of the mouth (said she felt as if something was pulling on it); temperature 99; pulse 80; respiration 20; for twelve hours; on account of pain refused subsequent injections.

CASE IX.

J. S.; colored; female; age 25; admitted September 19, 1912; confessed infection three years ago; no treatment; subsequent history and treatment indefinite; local examination disclosed general adenitis; six or more condyloma, one of which extends over the entire labia on both sides, including the rectum; mucous patches; mouth and throat foul with ulcers; September 28 neosalvarsan 0.6 grams; complained of no pain or tenderness following injection; slept well; temperature 99, pulse 110, respiration 26; following day, temperature 101, pulse 106, respiration 28; October 4, neosalvarsan repeated 0.9 grams; no pain; sleeps well; temperature 101, pulse 100, respiration 24. This case has shown great improvement; the condylomatous condition is greatly improved; stomatitis; complained of no pain whatsoever following the several injections.

Thus we have, of the series of nine cases, seven complaining of little or no pain and two complaining severely of the pain. In my opinion, the pain is caused more by the traumatism due to the amount of fluid injected, than to the drug itself. I believe, if it were possible to give the full dose of neosalvarsan in 1 c.c. of water, that there would be very little, if any, pain resulting. Ehrlich has advised that the drug be given in 20 c.c. water and Schreiber carried out this technique in his clinic, giving it up, however, on account of

the severe pain. I found that neosalvarsan dissolved very readily in 8 c.c. of water, and believe that, allowing a little more time for the drug to go into solution, it would readily dissolve itself in 3 or 4 c.c. It is my purpose in the future to use 3 or 4 c.c. of water with a few drops of a 1% solution of beta ucaïne, thereby making four injections of not over 1 c.c. each.

Ehrlich has declared on innumerable occasions that salvarsan is essentially an intramuscular injection, and only because of the pain involved in the intramuscular injection of salvarsan, he was compelled to advise the intravenous method. He was convinced that the results attained from the intravenous injection are not as lasting as the intramuscular, and he hoped that it would be only a question of time until a painless method could be devised. Therefore he now believes neosalvarsan is a step in this direction, its use having the smallest amount of reaction, followed by the enormous therapeutic value of the intramuscular method.

Wollbarst has used glycerine as a base, injected in 4 c.c. doses, but found this suspension very painful. Iodipin in 10 c.c. doses has also been advised and it is said it is very well tolerated. Nearly all of the investigators have used neosalvarsan with a 1% beta ucaïne solution.

The fact still remains that we may still expect the best results from the intramuscular injection; that its effects are far more lasting than the intravenous; that we cannot expect to gain a good technique without a series of fifty or more cases; and at present the results are indeed very satisfactory, giving us neosalvarsan, that can be used in the office by a physician inexperienced in its use with very little danger and with very little discomfort to the patient.

CONCLUSIONS AS TO NEOSALVARSAN.

1. Compared with salvarsan, results are at least as striking.
2. Larger doses can be given.
3. The reactions are practically absent.
4. The neutral reaction of the solution makes unnecessary surgical technique in entering the vein and obviates the use of sodium hydroxide.
5. A solution of 4 c.c. distilled water with a few drops of 1% beta ucaïne, should be a painless injection.

I desire to express my thanks at this time to Drs. W. B. White and E. W. Northcutt of my service, for their hearty cooperation and assistance.

DISCUSSION.

H. J. Farbach: I have used neosalvarsan in five cases and it has not been my experience that it can be given in larger doses than salvarsan; in fact, on the contrary, I have given it in smaller doses from the very beginning because of the statement of Ehrlich that it is more active than salvarsan, and even in diminished doses, I have seen more arsenical symptoms produced by neosalvarsan than by salvarsan. I give doses of at least one-fourth less than I give of salvarsan.

As to solubility, I will say that a dose of 0.1 gm. of neosalvarsan (representing 0.6 gm. of salvarsan) is readily soluble in 1 c.c. of water, but the reason I have not used it in such concentrated solution is that I feared the reaction would be so great as to cause an encapsulation. In a few cases I have given the neosalvarsan intravenously, and here, as well as when given intramuscularly, I have seen more evidence of arsenical intoxication than I have from salvarsan.

In regard to pain, the first few doses I gave were intramuscularly. Following the suggestion of Wolbast, I suspended the dose of neosalvarsan in 4 c.c. of glycerine, and added, drop by drop, a 1 per cent. solution of beta eucaine. It takes about fifteen or twenty drops to put this dosage in solution. That gave me about 5 c.c. of medicine, which I administered in four injections. The first two injections were absolutely painless. I did not see the patients for about thirty days after the injection, and they complained of nothing except a sense of stiffness for about an hour. The next three, given under the same technique, were apparently very painful. The patients were not confined to bed but, judging from the facial expression and the amount of opiate it took to control them, they must have suffered a great deal of pain. Then I tried plain water. The first injection of 8 c.c. with plain water, was painless, but the next three were very painful. The next technique I tried was the addition of a local anesthetic to the water solution, without any glycerine. This caused more pain than all the others put together. It is my experience that the old salvarsan, in suspension in oil, is a great deal less painful than neosalvarsan with the exception of a few instances. Reports of cases by other men who have given intravenous injections would seem to indicate that there was pain at the point of injection—a burning sensation where the needle passes through the vein. In cases where I have given it intravenously, the patients complained of no pain. One thing I have noticed in connection with the intravenous injection of salvarsan, is that the patient will complain of a peculiar taste in the mouth when about half the dose has been injected. I have not noticed this in connection with neosalvarsan, nor has any one else reported it so far as I know.

I believe that neosalvarsan has a great advantage over salvarsan in that all we have to do is to put it in water and it goes into solution.

As we all know, one of the greatest objections to the intramuscular injection of salvarsan has been that the solution is not good, and in some cases abscesses have developed following intramuscular injections of salvarsan, and in six weeks or two months after the injection when it becomes necessary to open the abscess cavity, practically the entire dose of salvarsan is found in it, having become encapsulated. Neosalvarsan will do away with all this. All we have to do in giving it intramuscularly is to keep away from the nerves, and we will have no trouble from it.

One thing we have to watch in giving either neosalvarsan or salvarsan is the unusual susceptibility of some individuals to the effects of arsenic. I have seen one fatal case, and my attention has been attracted to this feature more in connection with neosalvarsan than with salvarsan. Every one of my patients have shown evidence of jaundice for from three to five days after an intramuscular injection of neosalvarsan. All of them have complained of nausea and pain in the stomach, after either intramuscular or intravenous injection of neosalvarsan.

I have not followed the plan of giving larger doses at closer intervals; I have never given it at intervals of less than ten days. Two Englishmen have reported a series of about five thousand cases, and in this number all the fatal cases were those in which the dose had been repeated within ten days. I think this is of sufficient significance to cause us to be careful about repeating the dose until we learn something about the susceptibility of the patient to the influence of these new arsenic preparations.

Herbert Bronner: Dr. Day's report is a very interesting one. The point in which I was most interested was the doctor's statement that he believed in the future of the intramuscular method. I remember that, about a year ago, I made the statement, in this society, that the intramuscular method was the most efficacious, and in the light of recent literature on the subject, it appears that this statement has been substantiated. Those of you who are interested should read Dr. Fordyce's article in the last issue of the *Journal of the American Medical Association*, in which he makes the assertion that, from the standpoint of efficacy, there is no doubt that the intramuscular method is the best. This statement is also made by Captain Nichols, who has done a good deal of original work in this country with Dr. Fordyce.

As to the pain caused by the injection of either neosalvarsan or salvarsan, I cannot say that I have noticed much difference. I had the pleasure of following Dr. Day in his service at the City Hospital, and I noticed that most of them required at least one, and sometimes two, injections of morphine. In using the old salvarsan it was rarely necessary to give any more than this amount of morphine.

One point is that salvarsan oxidizes much more

readily than neosalvarsan, and in giving it by the intravenous method, unless one is an expert, if too long a time is taken in locating the vein, the solution is apt to become oxidized. Of course, in the intramuscular method, the technique is so simple that this need not be taken into consideration, but in intravenous injection it should be borne in mind.

Another point that has been mentioned is the temperature. We do not have to pay as much attention to the temperature of neosalvarsan as we did in using the old salvarsan. And, by the way, I will say that the men at the Rockefeller Research Institute do not pay near as much attention to the temperature as we have been accustomed to do here. I remember that when we first began to give salvarsan injections, we were instructed to keep the preparation at a certain temperature. This is entirely unnecessary in giving injections of neosalvarsan. In making a solution of neosalvarsan, the water should not be above room temperature.

It may be of interest to the members to know the practice in regard to administering either neosalvarsan or salvarsan at the Rockefeller Research Institute, where the most scientific work in this country is being done. They believe that one is just as efficacious as the other. I had an interview with Dr. Ellis who is doing the research work along these lines, and I asked him what their attitude was toward these preparations. He made this reply: "If one has a good right hand and an equally good left hand, why not use both?" They believe that we should use either neosalvarsan or salvarsan with mercury. Even in that institution, where they are doing work simply for the sake of investigation, they are not willing to do without mercury. The following is an outline of the way they handle these cases: They give two injections of neosalvarsan a week for three weeks, making six injections in all. The first dose is 0.75 grammes, and the next five doses are 0.9 gms. each. Then the patient is put on injections of salicylate of mercury for two months, followed by six more injections of neosalvarsan, which is in turn followed by two additional months of mercurial injections. That is the routine treatment. Of course, Wasserman tests are made every few days. This is what they call their "intensive" treatment, and it will be seen that they are not afraid of arsenical intoxication.

M. L. Ravitch: "The world do move." Last week we heard all about rheumatism phylacogens, knowing neither the etiology of rheumatism nor the composition of phylacogen, and now it is neosalvarsan. It is my belief that in ninety-five cases out of a hundred that are reported, we are not given all the facts. I recently had a patient who had a very severe form of latent syphilis. He did not want it to be known here that he had syphilis, so he asked me to send him somewhere for treatment. I sent him to a physician in St.

Louis who made four injections of salvarsan, and he came back here apparently perfectly well, but about two months later the same symptoms again manifested themselves.

I do not understand why, if we are going to use salvarsan, we should not use salvarsan alone, and not in conjunction with mercury. When we use mercury with it we cannot tell which does the work, the salvarsan or the mercury. In a symposium on the subject of syphilis at the last meeting of the American Medical Association, it was the opinion of many men that we should proceed very carefully in the use of salvarsan. Dr. Day has reported nine cases to-night, but he never mentioned that he examined these patients to ascertain whether or not any of them had kidney lesions, heart trouble, or any condition which might make the injection of salvarsan dangerous. Some time ago I saw a patient in consultation with a physician at Lexington, and I advised against the injection of salvarsan. Nevertheless, he administered it and the patient died. In using salvarsan we should examine the patient carefully for any condition that might contraindicate its use. Then in selected cases, use salvarsan alone, and see whether you get results from it.

J. A. O. Brennan: I am not so pessimistic as Dr. Ravitch. I believe that with good technique, clean instruments and a freshly made solution, there is very little danger in the administration of either salvarsan or neosalvarsan. I have given it only by the intravenous method, and I have never seen any bad results from it. I generally give it with mercury; never alone. I do not believe we can control the treatment unless we combine it with mercury. One man in Cincinnati gave salvarsan alone for a while, but I think he has discontinued that practice and now combines it with mercury.

Carl Weidner: In regard to the pain that follows the injection of salvarsan, I think this applies to practically any injection. Take the injection of mercury, for instance. Sometimes the patient will complain of no pain at all, and at other times they will suffer the most intense pain for twenty-four hours. It would seem that there must be some local condition to account for this. I would like to ask Dr. Day how he would explain it.

Geo. H. Day, (Closing): In regard to pain, I do not believe I have ever seen as much pain caused by anything as by the injection of bichloride of mercury. The only abscess I have ever seen from this cause followed the use of bichloride of mercury. I have given some four or five thousand injections and this is the only abscess I have seen.

There is only one man in the country who is now giving salvarsan alone in the treatment of syphilis. That is Wolbarst, of New York. I have discontinued using it alone and now combine it with mercury. I think every man who follows this line of work now knows that sal-

varsan alone will not cure syphilis. It is simply an eradicator of symptoms. One of the most severe cases I have ever seen was a patient in New York, to whom Dr. Young had given four injections of salvarsan, and the man had a negative Wasserman reaction at this time. He had complete loss of voice. He was shown to a medical society there, and it was remarkable how many lesions this man had, in spite of the fact that he gave a negative Wasserman reaction and had received four intravenous injections of salvarsan. I think it is generally believed that mercury is of just as much value now as it was before the discovery of salvarsan.

In regard to Dr. Ravitch's remarks, of course he knows that no one would undertake to administer salvarsan, or anything else for that matter, without having first carefully examined the heart, kidneys, etc. That is understood.

SALVARSAN TREATMENT; FATAL TERMINATION.

(REPORT OF CASE.)

By H. J. FARRACH, Louisville.

Patient, male, age 52, unmarried, traveling salesman, Irish descent. No severe illness at any time in life.

Contracted syphilis thirty years ago. Had chancre and secondary eruption. These disappeared promptly under treatment. Continued treatment for one year. No evidence of the disease in after years except an occasional sore in the mouth which disappeared without treatment.

Habits: Not a dissipated man, very moderate drinker, no sexual excesses but a continual smoker.

Present condition began some six months ago with soreness and irritation on swallowing. These symptoms gradually increased until they reached such severity that the pharynx had to be cocaineized before patient could swallow anything. This condition had been present for five weeks when patient was first seen. Had lost 80 pounds and the only nourishment taken was two ounces of milk or eggnog three times a day.

His condition was extreme. He was so debilitated he could hardly walk, there was a continual coughing and an abundant expectoration of a foul necrotic discharge. A diagnosis of pharyngeal tuberculosis had been made and he had received treatment accordingly. He had not received any arsenic, mercury or iodides.

Examination showed a large, ulcerating gumma involving the pharynx and part of the soft palate. Frequent examination of the pharyngeal secretion failed to show any evidence of the tubercle bacilli while the blood

serum was four plus (positive in both the Wasserman and the Nogonchi modification).

Iodides and mercury were administered, the latter in the form of the salicylate hypodermically. On the fifth day mercurialism was manifested by tender gums and frequent mucous stools. The throat condition was little or no better and patient complained of continual pain.

On the morning of July 8, 1912 0.3 gm. of "606" was given intravenously. During the injection the patient complained of a sticking, burning, "hot" pain in the throat and in the right side in the region of the liver. This continued until the beginning of the rigor some thirty minutes after the injection.

This rigor while intense was not severe and lasted some fifteen minutes. Two hours after the injection the chart showed temperature 102, pulse 146, respiration 32. Five hours after injection temperature 99 2-5, pulse 136, respiration 34. Seven hours after the injection temperature 98, pulse 88, respiration 24. Patient at this time showed a great deal of improvement. He drank water freely with no pain and expressed a desire for food. Kidney, skin and bowel action good. Cough greatly lessened but patient expectorated large pieces of necrotic tissue. Subjectively and objectively patient's improvement was little less than marvelous.

This condition of affairs continued for twenty-four hours. He had a good night and was taking all the nourishment given. Between the twenty-fourth and thirtieth hour after the injection he began to complain of feeling cold and of pain that seemed to be referred to the lower abdomen. Chart at this time shows temperature 94 2-5, pulse 80, respiration 20. In the following thirty hours the temperature was never above 95 3-5. The pulse was of good volume, ranging between 90 and 100. Excretion of urine for twenty-four hours was twenty ounces. Four low enemas within eight hours resulted in nothing but a greenish discoloration of the water.

During this period a severe muscle soreness developed. No pain in joint motion but muscles so tender that mere touch caused the patient to cry out with pain. He also complained of severe pain in the throat that was increased on swallowing.

In the next twenty-four hour interval the temperature curve was upward until it reached 99 4-5, pulse 100, respiration 26. In this interval no urine was passed and catheter procured but one-half ounce. Extreme muscle tenderness was still present with pain in the throat. Wrist drop was evident on right side and there was some disturbance of mentality, shown by flighty, disconnected conversation. Agents to increase renal activity were used

and within twenty-four hours were rewarded by a good flow of urine.

During the latter hours of this period evidence of jaundice was noticed and within the next twenty-four hours the jaundice was complete, even to the sclera and nails being colored a deep yellow. An intense general itching was present also. Chart during this period showed temperature between 96.3-5 and 97.5, pulse 80, respiration 26.

Within the following forty-eight hours the patient improved decidedly. Muscle soreness was less, there was little pain in the throat and he was taking nourishment and water at frequent intervals. The wrist drop was not so evident and the mentality clear. Temperature, however, was low, 97, and the jaundice still complete. Urine showed large amounts of bilirubin.

Patient retired on the night of July 14, 1912, feeling greatly improved and in good spirits. Went to sleep readily and slept well until 3 a. m. He began muttering in his sleep and became very noisy at times. At four-thirty he was aroused with difficulty and expressed severe pain on attempting to swallow. Chart at this time shows a temperature of 94.5, pulse 88, respiration 28. Pulse soft and of low tension. Mental condition increased, very restless and much muscle twitching. Bowels acting involuntarily, catheter procured four ounces of deep, bile stained urine. Continued in comatose condition and died in coma at five thirty p. m. No post-mortem allowed.

The question of the urine before the injection of the "606" and during the days that followed is of some interest. Five days before the injection it showed a trace of albumin but no casts. The morning of the injection it showed no albumin or casts but mercury was present. Ten hours after the injection there was a trace of albumin and a few hyaline casts and this condition of the urine from a renal standpoint was present throughout the severity of the condition. Even in the half-ounce obtained in twenty-four hours there was little albumin and few hyaline casts. The urine obtained on the last day was loaded down with albumin and casts. Bilirubin appeared at the same time the jaundice was noted and steadily increased in amount.

The potent question in this case is; was the condition that began twenty-four hours after the injection of "606" due to arsenic or was it due to the toxin liberated by the action of salvarsan on the treponema. That it was due to the salvarsan I think there can be no doubt.

The symptoms of acute arsenic poisoning are of one of two groups, those of the gastrointestinal type or those of a profound narcotic character. In the former, and the one most

commonly seen, there is a burning pain in the throat and stomach, tenderness in the abdomen, vomiting, great thirst, suppressed urine, frequent bloody mucus stools, rapid and feeble heart action, great anxiety and finally collapse. Associated with these symptoms are those of edema of the eyelids, epigastric tenderness, dyspnoea, disordered sensibility, urticaria and jaundice.

In this case there was no vomiting or thirst, the urine was not loaded down with albumin or casts, until the last day, the heart was not rapid (92), there was no anxiety on the part of the patient, nor was there any edema of the eyelids. But there was burning in the throat epigastric tenderness, severe muscle tenderness, suppressed urine, wrist drop and these followed by an intense jaundice.

In argument against the arsenical poisoning and for the toxin liberation by the destroyed treponema are the facts that the condition did not begin until twenty-four hours after the intravenous injection, that most of the symptoms can be explained by the action of such toxins, that there was a lesion in the liver as well as in the pharynx and the lack of kidney evidence of such a severe metallic poisoning.

I have given a good many, (sixty-five) intravenous injections of "606". I have noted the action of the so-called liberated toxins and have seen them in varying degrees of intensity but I do not believe the symptoms in this case can be explained on these grounds. If this was arsenical poisoning then the statement that salvarsan has but a slight or no toxic effect on the human body cell and a highly toxic action on the treponema is not true in every instance.

Of the preparation and chemical properties of the solution given in this injection there can be no doubt.

The explanation that this patient was peculiarly susceptible to arsenic is of course adequate, but how are to discover this idiosyncrasy before the injection?

DISCUSSION.

S. G. Dabney: I think the medical profession of Louisville is greatly indebted to Dr. Farbach for such work as he has reported to-night. Progress in medicine and knowledge of new remedies would be greatly enhanced if we had such frank statements from all members of the profession. I feel quite certain that only a small proportion of fatalities following the use of new remedies are reported.

Just a word about Dr. Farbach's case. This patient was referred to me from Southern Illinois some time during the month of July. I was out of the city at the time and the case was turned over to one of my colleagues, who sent him to Dr. Farbach. I returned to Louisville on the day af-

ter the injection of "606". Dr. Farbach has given a very graphic description of the case, and there is nothing I can add to it. My impression, however, was that he was a harder drinker than would be inferred from Dr. Farbach's statement. Another impression I received was that this patient was a very sick man; that he showed great exhaustion and was very ill when he arrived in Louisville. I got this impression from the nurses and from other people who had seen him rather than from the doctor.

The previous treatment of this case is of interest. Usually, in these cases of late syphilitic manifestations, if we will take the trouble to get a history of the course of the disease and treatment, we will rarely find that the treatment was continued for more than eighteen months, and the majority of them will give a history of only a few months' treatment. Here was a man who had undergone treatment for only a year at the longest, and very likely it was superficial treatment at that.

The lesion in this man's case, as the doctor described, was a very extensive gummatous infiltration of the pharynx, also involving the palate, which had broken down. Of course, nutrition was greatly interfered with, both because of the disease itself and because of the very great difficulty that the man experienced in swallowing.

Just a word or two about this remedy, "606", which has attracted the attention and interest of the medical world everywhere. To the vast majority of cases syphilitic symptoms yield promptly, sometimes even amazingly, to mercury and potash. The real problem would seem to be these late manifestations, classed as para-syphilitic—such as optic atrophy and Tabes dorsalis. It remains to be seen what influence "606" will have in preventing or curing these conditions—certainly its immediate effect on the nervous symptoms is sometimes disastrous. It does not appear to me that there is anything like the enthusiasm in regard to the preparation that there was a year ago. The idea that syphilis can be cured by two injections of salvarsan has been given up, and the majority of men to-day combine mercury with it. "606" certainly has very untoward immediate effects upon the nervous system; what the final results will be of course we cannot say. A number of fatalities have been reported following its administration. Recently, a gentleman in St. Louis read a paper before the American Medical Association, reported four cases in which death from encephalitis occurred following treatment with salvarsan. On the other hand, in this particular instance, there were several good reasons for the use of the drug. In the first place, the man wanted it; he told me so himself. After reaching the city I talked the case over with him. He said he knew he was in a bad way and was willing to take anything that offered any hope. In the second place, the patient was undoubtedly a very sick man; the

extreme exhaustion and extreme cachexia had progressed so far that it is doubtful if any remedy would have saved his life.

I am very glad to have heard this report, and I think we should all feel grateful to Dr. Farbach for it.

Herbert Bronner: Dr. Farbach was kind enough to tell me about this case at the time and there was no doubt in the minds of either of us that death in this case was directly due to arsenical intoxication. It may be of interest to the society to know that, at about the same time that Dr. Farbach had this case, Dr. Keyes, of New York, reported a case so very similar to his that it is really remarkable. Keyes' case was a young man in robust health. He stated that the urine had been examined and found absolutely normal. He also stated that there was no change in his technique; that he used the same method as heretofore, being careful to carry out Ehrlich's injunction to use perfectly distilled, sterilized water, so that there was no possibility of error in this respect. Keyes' patient developed the same symptoms that Dr. Farbach reported; namely, marked jaundice and involvement of the kidneys. However, this patient did not develop the wrist-drop present in Dr. Farbach's case. In Keyes' case the symptoms likewise appeared in 48 hours, and for three or four days the patient voided no urine, the small amount excreted being withdrawn by means of a catheter. Keyes' patient died on the seventh day. I think Keyes' conclusion was that death was due to arsenic poisoning.

Brown and McKenzie, in their late work on syphilis, report a series of fatal cases following the use of salvarsan in which they had an opportunity of making post-mortems, and in several cases the patient had jaundice and acute nephritis.

Three other deaths have recently been reported but, unfortunately, the cause of death was not given. As Dr. Dabney mentioned, in two cases death was ascribed to encephalitis.

It seems to me that the important lesson to be learned from this report is that we have no means of knowing when a patient has an idiosyncrasy for arsenic. For that reason, if we can discover some method of intramuscular injection that is not painful, it will be less dangerous to the patient, because, by the intravenous method the drug is thrown directly into the circulation and the patient has no chance, whereas, if given intramuscularly, absorption is slower and if any untoward symptoms arise we can simply make an incision and release the arsenic.

Geo. H. Day: I would like to ask Dr. Farbach if he does not think that, in such cases as he reported, it would be well to divide the doses, or, better still, give it in the form of suppositories? I believe that if we will divide the doses and give small doses until the patient gets stronger, and then begin intravenous injection, we will get

better results in cases like that of Dr. Farbach's.

H. J. Farbach, (Closing): This case taught me one thing. I saw, through the courtesy of Dr. Day, a negro who was in practically the same condition as the case reported. The ulceration was so bad that it was necessary to do a tracheotomy. The secretion could not be kept out of the bronchial tubes and it would almost choke him to death. That man has had no treatment whatever for two weeks and still he is getting well.

Geo. H. Day: I gave him two doses of "606".

H. J. Farbach: In the case reported I used "606" as a terminal measure, as it seemed that he would certainly die without it. I am led to believe that "606" is contraindicated in syphilities that are greatly emaciated and depressed. To-day I saw a case of ulcerating gumma of the epiglottis, and I believe it will be far better to put this man on iron and cod-liver oil and build up his fighting forces, and then, if he will not respond to mercury, give him the arsenical preparation. It may be that, in this depressed state of metabolism, the chemical elements or cells of the body are different from what they are in a robust state, and that under these circumstances the preparation unites with the body cells as well as the bacteria. Therefore, I think we should be very careful in the use of salvarsan in cases where there is great emaciation and depression.

GALL-STONES IN THE COMMON DUCT.

(REPORT OF FIVE CASES WITH SPECIMENS.)

By JNO. R. WATHEN, Louisville.

In presenting the report of these five cases and exhibition of the specimens removed, I would call attention to the fact that gall-stones in the common duct are reported in about one case in every ten by the surgeons who have had the very largest experience and in the hands of the average surgeon about one in every twenty-five cases.

This is probably due to the average operator being content to remove those from the gall-bladder and not being very careful or enthusiastic about a further search of the bile ducts, or at least not having the proper technique or instruments for this later procedure, or even not fully appreciating the anatomy of these parts.

While it has been estimated that jaundice occurs in only about 14% of cases of gall-stones, it has been well established that gall-stones in the common duct give rise to jaundice in the majority of cases, probably in about two-thirds of the cases. If the stones remain in the gall-bladder the pathology remains local, but when they attempt to pass out and reach any portion of the common duct, they then cause damage to organs which are very essential to life as the liver and the pancreas.

As the gall-bladder has no lymphatic glands and few lymphatic channels, we can understand how stones may remain for long periods without causing pronounced symptoms, but when they pass out and obstruct the common duct we have pain and often a high fever, 103° to 107° F.

Mayo claims a mortality of 2.75 per cent. for 4,000 operations for gall-stones. Where the disease was local and confined to the gall-bladder and cystic duct a 1.8 per cent. mortality. In 492 cases in which the common duct was involved a mortality of 8 per cent.

Mayo further says: "The removal of stones from the common duct during the quiescent period gave a mortality of less than 3 per cent.; in the cases marked by active cholangitis with jaundice the mortality was about 10 per cent. Where there was complete obstructive jaundice, that is, no bile in the ducts, the mortality was nearly 25 per cent."

The following cases I wish to briefly report:

CASE I.

Mrs. K., of Louisville, age 59 years, widow with two grown children. Previous history negative. Had complained of chronic indigestion for a number of years. Gall-stone colic at frequent intervals for one year before operation. When I first saw her she was badly jaundiced, could eat almost nothing, had lost much weight and was suffering from colic at frequent intervals. Temperature and pulse would be variable. Operation revealed a large thickened gall-bladder containing over 100 gall-stones. Many adhesions. Careful exploration of ducts located three stones in the first portion of the common duct. These were removed and drainage instituted. Patient made uneventful recovery and jaundice cleared up.

CASE II.

Mrs. C., of Elizabeth, Ind., age 45 years, had complained of chronic indigestion for a number of years, with occasional attacks of pain and vomiting. Upon examination found marked tenderness in region of appendix and also some slight tenderness over gall-bladder. Patient was slightly jaundiced, temperature and pulse about normal.

Operation showed a chronic inflamed appendix with adhesions and also adhesions around gall-bladder. Appendix was removed and when gall-bladder was opened 143 stones were found. Common duct explored, by Mayo probe, and four small stones removed from first portion of common duct. These stones were held tightly in place, and it was surprising how little jaundice patient showed considering this fact. Patient made a nice recovery.

CASE III.

Mrs. K., of Corydon, Ind., age 26 years. When first brought to the city was found in a very weak and emaciated condition, badly jaundiced, temperature 103°, pulse 120 and suffering much pain.

Rested and prepared patient for 48 hours and at operation removed 275 gall-stones from the gall-bladder, two stones from the cystic duct, one from the hepatic duct and three from the first or second portion of the common duct. Patient made a good recovery.

CASE IV.

Mrs. D., of Louisville, age 41 years, complained of occasional attacks of gall-stone colic and acute indigestion. When first seen by me in consultation she was much jaundiced, suffering pain requiring a 1-4 grain morphine to relieve, and vomiting all food she attempted to take into the stomach.

Operation revealed a very large, dilated gall-bladder, which, when opened, contained a thick black bile but no stones. Upon further search I discovered a large stone at the juncture of the hepatic, cystic and common duct. I made every effort to get the stone back into the gall-bladder but without success. I then incised the duct and removed the stone, only after I had crushed one end in the effort. This patient died six hours after operation from shock.

CASE V.

Mrs. P., age 50 years, of Hazard, Ky. When first seen on arrival in the city, I found her deeply jaundiced, high fever, rapid pulse and with a history of gall-stone colic at intervals for a long time. Patient had lost much weight and from general appearance I was inclined to believe we had a malignant condition of the head of the pancreas to deal with. After a few days' preparation by the usual measures I opened over the gall-bladder region, and found a small, thick and contracted bladder, which, when opened, contained only a clear fluid. The cystic duct was strictured and upon further examination I found a much dilated hepatic and common duct. In the first portion of the common duct was a large stone embedded tightly. This duct was incised, stone removed, and drainage made. Patient recovered.

DISCUSSION.

Louis Frank: I wish to call attention to just one point. The impression one would get from reading this report (while it may not be what the doctor intends to convey) is that operations for stone in the common duct are attended by comparatively little danger and a rather low mortality. As a matter of fact, operations for stone in the common duct are among the most dangerous

procedures in abdominal surgery. When these operations are done in the presence of profound jaundice, rigors and temperature, the mortality, as has been stated by men of large experience, will be far greater than this report would lead one to believe; in fact, from conversations that I have had with a number of men who have done a great deal of work along this line, the mortality in these cases is about 90 per cent. I make this statement because I do not believe the impression should go out that the mortality in these cases is as low as 10 per cent, or even 25 per cent. Furthermore, I believe it is the consensus of opinion among men of the best judgment that operations should not be done in the presence of jaundice, rigors and temperature if it can possibly be avoided. I think the men who have seen a great many of these cases will bear out the statements I have made.

W. C. Dugan: Dr. Frank has made a point that I wish to emphasize, and that is against radical operative interference in the presence of profound jaundice. I believe these cases should be drained. I remember a patient that was brought into St. Joseph's Infirmary one night with a temperature of 104, very rapid pulse and frequent chills. I am sure that patient would have died had I attempted to do a major operation. I opened the gall-bladder and established drainage. The patient recovered and went home, but returned in a few weeks for operation for the removal of a stone in the common duct, which was successful. I am sure I would have lost that patient had I attempted a major operation when I first saw the case. The jaundice and intense sepsis makes these very unfavorable cases.

In regard to the small stones Dr. Wathen mentioned, I do not think we should open the duct in these cases. I have never seen one of these stones that failed to come back through the drainage tube. Where you have a large number of small stones in the gall-bladder, and you find the same character of stones down in the duct, we should treat them in this way. It is the large single stone in the common duct that we have to take care of; the small stones will take care of themselves.

I want to go on record as opposing radical operation in these cases where the patient is in bad condition. Drain the gallbladder, get your patient in as good condition as possible and then do a radical operation.

J. Garland Sherrill: This discussion has reached a point where I feel that I want to say something. We all agree that prolonged, persistent jaundice cripples the patient's resistive powers, renders him more liable to be subject to hemorrhage, and destroys the kidney and hepatic functions. Consequently, it adds greatly to the risk of the operation. However, I do not believe any one here would refuse to operate upon a case of infected stone in the common duct, which was

jeopardizing the patient's life, simply because that patient had jaundice. I believe it is bad teaching to say that we should leave these cases alone and depend upon drainage by flushing the alimentary canal where we have a stone impacted in the common duct. When you drain the gall-bladder the shock to the patient is just about as serious as to complete the other part of the operation. It takes only a few minutes longer and the results obtained are so much better than I do not believe we are justified in closing up these cases where we know that there is a stone in the common duct, without removing that stone.

Jno. R. Wathen, (Closing): I have never heard anything that surprised me more than Dr. Frank's statement that the mortality in these cases is 90 per cent in the hands of the best men. In my experience the mortality has been about the same as that of Mayo and others—about 20 per cent. I believe that, in more recent reports, Mayo gives the mortality as 25 per cent., but I am rather surprised that any one should have such a high mortality as 90 per cent. If you will recall the histories of these cases, you will remember that I did not operate on these patients the first time I saw them, but prepared them for several days. I removed the small stones with a pair of forceps and the large ones by cutting into the duct and establishing drainage.

MULTIPLE, SESSILE PAPILLOMATA OF THE LARYNX.

By W. D. LEVI, Louisville.

Mr. S., came to me on May 31st, last. He is 31 years old and a planer by occupation. He has been in perfect health since childhood, but gives an unsatisfactory venereal history. For the three years prior to this trouble, he called three or four large dances a week for six or seven months a year.

The condition began with huskiness, which slowly increased until his voice was reduced to a whisper and respiration was embarrassed.

He at no time experienced pain and has coughed nearly none.

Twenty-eight months ago while residing in Denver he consulted a throat surgeon. The patient was first saturated with potassium iodide for two months on the hypothesis that the growth might be a syphilitic granuloma. This medication was *negative*. Then an intra-laryngeal removal was done. The tumor tissue on microscopical section was diagnosed papilloma. The papillomata were removed in some sixteen operations through the natural opening. His voice, though not regaining the normal was restored after the first few operations and the respiratory embarrassment relieved. He left Denver last December and between then and last May these (exhibiting specimens) papillomata recurred.

When he came to me the anterior half of

the glottis was choked with these sessile cauliflower-like tumors. He was hoarser than now and had difficulty in breathing when he stooped over in his work.

On July 27, we did our fourth and last operation and since then he has had no treatment but spraying the larynx with 95% alk. which he does daily.

There are now to be seen recurring growths on the laryngeal surface of the epiglottis and others on the anterior surface of the hypolarynx just below the cords. I am reporting this case in order to get suggestions on methods to prevent repeated recurrences of this tumor.

DISCUSSION.

Gaylord C. Hall: I was able to get only a superficial view of this patient's larynx. I think Dr. Levi is to be congratulated upon clearing up the case as thoroughly as he has, and from what I was able to see, it should not be difficult to deal with the remaining papilloma and effect their complete removal by intra-laryngeal operations. As we all know, papilloma of the larynx is most apt to be recurrent in children; as the age advances the tendency to recurrence decreases. In view of this man's age, I should think that under repeated intra-laryngeal operations, he should in time become entirely free from the trouble.

I would like to suggest one thing to Dr. Levi in connection with this case. I have had several of them and have run the gamut of applications, and I can suggest a better remedy than 95 per cent. alcohol application to the larynx. One remedy that I have found will influence these growths favorably and decidedly, is formalin solution. First, begin with a weak solution, 2 to 5 per cent., and gradually increase it to 10 per cent. I have not seen a case that could stand a stronger solution than 10 per cent. I remember particularly a case I had in a young lady schoolteacher, who had entirely lost her voice as the result of the development of a papilloma in the larynx. After having been repeatedly operated upon, she finally came under my observation, and by the same method of operation which had previously been without result, plus the application of formaldehyde solution, the trouble entirely cleared up, and there has been no recurrence in the four years that have elapsed since that time.

In children, I think it is best to do a tracheotomy, without any attempt at intra-laryngeal operations, because of the fact that these growths recur so rapidly that it is practically impossible to get rid of them by operation. By doing a tracheotomy, however, thus putting the throat absolutely at rest, the condition will very often clear up in two or three months and not recur.

I remember a little colored boy who came under my observation during my service at the City Hospital, some four years ago. By intra-laryn-

geal operations I was able to remove the papillomata, but told the mother that they would likely recur and that at the first sign of recurrence she must bring him back. When I next saw the boy he was almost completely asphyxiated, and practically moribund. I took him to the University Building and did a tracheotomy. I injected a little cocaine, made a hurried incision and put in a tube.

Dr. Secord Rarge, of Cleveland, recently suggested a method of locating the trachea in these cases. He uses a large, curved needle threaded with silk, passing the needle through the skin and muscles on either side of the trachea, and then making the incision between. By this means the trachea is held in place and does not fall away with the respiratory movements.

In the case mentioned, after tracheotomy had been done the child was put in the ward, with the usual accompaniments of steam-heated air and vapors. He did badly and for a while I thought he was going to die. This was in the winter-time. Finally, the Superintendent and myself devised a window tent, we put him out in the cold, and thereafter the case was treated exactly as we treat pneumonia in children. He got along beautifully and finally recovered.

Regarding laryngeal papillomata in general, I would say that in the recurrent form in children, tracheotomy should be done. In older patients, if we will persist in intra-laryngeal surgery followed by applications of formaldehyde solution to the bases of these growths, I think the majority of these cases will clear up without any trouble.

J. M. Ray: I have seen a number of these cases, both in children and in adults, and I agree with the last speaker in one respect: that in children, the best treatment is either intubation or tracheotomy. I had two cases in which I introduced a tube which they wore for from three to six weeks. The pressure of the intubation tube causes absorption of the growths and there is usually no recurrence. At the present time I have under observation a child with papilloma of the larynx, which I have had to treat by intra-laryngeal methods. I intubated this child several months ago, but the tube would not stay in. The child would cough it out in two or three minutes. As long as the child is not embarrassed in breathing, I propose to let it alone, but if it should develop difficulty in breathing, tracheotomy will be done. In most instances, after putting in a tracheotomy tube and resting the larynx, these growths will disappear, and the only trouble we have afterwards is to get rid of the tracheotomy tube, which is almost as hard as getting rid of the growth itself.

I have had several cases of laryngeal papilloma in adults, and they will persist in recurring. I think Dr. Levi referred to one case that has been reported in which there were twenty-nine recurrences.

As far as local treatment is concerned, I do not think an alcohol spray does much good, because most of it goes into the stomach and very little of it gets into the larynx. As to formalin, I have heard that recommended, and I used it faithfully in the child I mentioned, but without any effect.

I would make this suggestion to Dr. Levi in connection with his case: I believe if he will introduce a direct laryngoscope and pinch these growths off, and then make application of alcohol and formalin to the bases of the growths, it will have a beneficial effect. Then have the man come to the office every day or two, and put in a laryngoscope and swab out the larynx.

S. G. Dabney: I congratulate Dr. Levi upon the successful conduct of the case thus far. My experience has been about the same as that related by Dr. Ray and it would be merely repetition for me to discuss the case farther.

Adolph O. Pfingst: It may be of interest to know that some of the German laryngologists have been using radium in the treatment of this form of tumor. They apply it through an aluminum tube passed to the larynx through the mouth. In cases which have progressed so as to invade the under surface of the cords, they advise that a tracheotomy should be done and the radium applied through the tracheotomy wound.

I would like for Dr. Levi, in closing, to state whether in his experience in Vienna, he has ever heard or seen anything in regard to the use of arsenic internally in these cases. I have read of its use and recently saw a case in which it had been given, however without success.

W. D. Levi, (Closing): Answering Dr. Pfingst's question, I will say that Herbert Tilley, of London, recommends the use of arsenic where there is some constitutional indication. However, so far as I have been able to learn, constitutional derangements do not have much effect upon these growths. I do not know anything about the use of arsenic in Vienna. I have noticed that a good many men recommend it, but I do not think it indicated in such a robust individual as our patient.

As Dr. Pfingst says, most writers on the continent and in England have advocated the use of arsenic in these cases, particularly where there is some constitutional defect indicating arsenical medication. This patient is unusually healthy and so far as I am able to learn constitutional derangements play at most a small part in the etiology of tumors.

I shall be interested in trying formalin topically in this case.

MEDICAL PROGRESS

DEPARTMENT OF GENERAL MEDICINE

Fibrillation of the Auricles; Its Effect Upon the Circulation, by Thomas Lewis, M. D.:—Auricular fibrillation, so designated by Lewis about three years ago, was first described by Mackenzie as "nodal rhythm," and consists of very rapid fibrillary contractions of the auricles, preventing their normal systolic action.

Examining more than one hundred patients with heart failure and irregular pulse, Lewis was able to demonstrate by the electrocardiograph the presence of auricular fibrillation in seventy per cent., and he regards it therefore as the most common form of irregular heart action in man—a conclusion now generally accepted.

The observations here reported are based on the results obtained by experimentation upon a very large number of animals.

Under normal experimental conditions the inception of auricular fibrillation caused the ventricles not only to assume an irregular rhythm, but their action became also accelerated from 50 to 100 per cent.

The blood pressure changes were carefully studied, and were found wholly dependent upon the amount of blood thrown into the arteries by the heart, no vaso-motor action of the periphery being manifested. His experiments show that in simple tachycardia a considerable acceleration of the ventricles may occur without change of arterial pressure, or that such increase of rate may be accompanied by a slight rise or fall of the pressure, but as higher rates are reached a fall in the pressure always occurs, increasing the proportion to the increase in the heart rate. This proves that the rate is a predominant factor in producing the usual fall of blood pressure. The venous pressure was found to move, as a rule, in the opposite direction from the arterial pressure. "We may conclude, therefore, that the changes in arterial pressure are due solely to the change in the mechanism of the heart beat and we may seek the cause of all circulatory pressure changes in this organ." It is further observed that the fall of arterial pressure is less profound when the ventricular action is regular than when the regularity is disturbed. As a reason for this difference Gesell has emphasized that normally the auricles aid in ventricular filling to an extent which cannot be questioned. This argument is met by Lewis, who believes the auricular fibrillation instead of a fall of blood pressure may remain unaltered, or may actually rise. The absence of auricular filling of the ventricles, as when the

auricles fibrillate, seems to him to be almost if not quite compensated for by increased venous pressure, which ensues when the arterial pressure falls.

In auricular fibrillation the rate of ventricular action is one of the most important indications of the gravity of the condition as a whole.

When the auricles pass into fibrillation the mean volume of the heart decreases. This reduction in size is observed whether the arterial pressure rises, falls or remains stationary. It is due entirely to change in the size of the ventricles. Up to a certain point the greater the acceleration, the greater the reduction of the volume of the heart. The heart is small at all phases of its beat. The decrease in the heart volume is independent of the velocity of the flow through it. The flow is usually reduced, with consequent fall of blood pressure, but it may be increased producing a rise above the initial pressure. The decrease of heart volume appears to result from purely mechanical causes; shortening of the diastolic periods as a result of the acceleration is sufficient alone to account for it. Section of all the cardiac nerves does not interfere with the reaction. In the human subject the onset of auricular fibrillation is often accompanied by obvious increase of volume. On a few occasions dilatation occurred in the present series of experiments. This reaction was probably due to nutritional changes in the ventricular muscle.—*Journal of Experimental Medicine*, Oct. 1, 1912. F. C. A.

Expulsion of Pleuritic Exudate by Inflation, by I. Holmgren, Stockholm:—This method has decided advantage over spontaneous absorption when the exudate is moderate or extensive in size. The deposit of fibrin, followed by connective tissue proliferation and contraction of the lung, which usually results from ordinary effusions of the pleura when left for spontaneous absorption, can be obviated by Holmgren's method of inflation, which at once effectively clears the pleural cavity of its contents. The procedure is also to be preferred to ordinary aspiration, inasmuch as all the exudate can be removed at one sitting and without much discomfort or danger to the patient. As aspiration is ordinarily performed care is taken that only 1000 c.c. or, at most, 1500 c.c. be removed at one time. The reasons for this are partly the risk of inducing such symptoms as cough, chest pains, dyspnoea, anguish, etc., and even oedema of the lung, due to a considerable reduction in the intrapleural pressure, and partly the expectation that the removal of a small amount of exudate will give an impulse to a speedy spontaneous absorption, rendering a complete evacuation unnecessary.

When inflation is practiced these reasons do not obtain. The pleural sac is at once completely emptied and in place of the effusion a quantity of air is left, preventing too great a reduction of the intrapleural pressure and at the same time separating the walls of the pleura, thereby reducing the chances of adhesions to a minimum. No disadvantage from this artificial pneumothorax has been observed, although in some cases it must have persisted for more than a month. Other writers who have practiced the Forlanini method of inflation for pulmonary tuberculosis have found that the elasticity of the lung remained unimpaired after a compression lasting from one to two years. However, when a more rapid expansion of the lung is desired the pleural sac may be inflated with compressed oxygen instead of air.

On account of the lesser strain upon the elasticity of a damaged lung and the lesser liability to reopen a perforation, besides a more thorough evacuation of the pleura, the inflation method is to be preferred to ordinary aspiration in cases of tubercular empyema, pyopneumothorax, and hydro-pneumothorax. Holmgren considers, therefore, this method indicated in all cases of pleuritic effusions, except when the exudate is so slight that its spontaneous absorption can have no bad results.

TECHNIQUE.

The skin is painted with tincture of iodine, and a 1% solution of cocaine or novococaine is injected hypodermatically at the point of thoracentesis. A trocar is inserted in the tenth intercostal space, between the scapular and posterior axillary lines. After the point of the instrument has entered the cavity, it is directed upward to avoid injury to the diaphragm. A rubber tube is then attached to the trocar and the exudate is allowed to escape by virtue of the intrapleural pressure.

Another trocar is now inserted at a higher point for the purpose of inflating the pleural cavity. Through a rubber tube this trocar is connected with a Potain bottle or a similar contrivance partly filled with water and so arranged that air is forced by a pump or atomizer bulb through the water in this bottle and into the tube of the trocar, thus reaching the pleural cavity. The purpose of the water is simply to afford an estimate of the amount of air employed. Sterilization or filtration of the air to be injected is unnecessary for no infection from this source has been observed. Comparison is made with the opening of the peritoneal cavity in tubercular peritonitis, where a free access of air seems decidedly beneficial.

During the aspiration the pleuritic fluid will flow through the tube of the lower tro-

car until the intrapleural pressure plus the pressure of the fluid in the tube, becomes equal to the atmospheric pressure. The negative pressure in the pleural cavity which thus ensues results in an undue distension of the lung, producing chest pains and coughing. By forcing air through the upper trocar the discomfort ceases almost instantly, and the flow starts again. To avoid all discomfort a small amount of air may be injected in advance of the oncoming symptoms, and the process is repeated until the exudate is entirely removed. The escape of the last drops of fluid will be favored by raising the outer end of the lower trocar, and when the cavity is empty only air will pass through the tube. At this time the pleural cavity will be in direct communication with the atmospheric air, which now exerts an equal pressure upon the outer and inner surfaces of the lung, thus affording an elastic pulmonary equilibrium. While at the beginning of the thoracentesis the pressure within the pleural sac was increased, compressing the lung, it will be found that during the inflation the lung will expand.

Should more air be injected than the escape of the serum would warrant, the patient would complain of a sensation of thoracic constriction. This is a signal to stop the inflation until a sufficient quantity of the exudate has escaped, or if more speedy relief is desired, the stopcock connected with the upper trocar may be turned to release the excess of the injected air. Much discomfort or danger from this cause is not incurred.—*Hygica*, Stockholm, Sept. 1910. F. C. A.

The Vasodilators. In the August number of the Monthly Cyclopedica, Francis Ashley Faught presents a consideration of vasodilators as a group, emphasizing three important points: 1. The absolute necessity of applying the blood-pressure test as a logical and the only accurate means of acquiring definite information concerning the condition of the circulation, and the indications for its modification and control. 2. The mere finding of an elevated blood-pressure is not necessarily an indication for its reduction. Indeed, the latter should never be attempted unless there is a good and sufficient reason, based on the careful study of the case, for doing so. Long continued high pressure often becomes a necessity to the organism, and if it is interfered with the patient's circulatory equilibrium will be destroyed and disaster result. 3. Drugs by no means constitute the only agency we have for successfully combating hypertension. They are often not indicated when the same results can be better and more permanently accomplished by other means, including diet, hygiene, hydrotherapy, exercise and electrical treatments. The vasodilator group of

drugs belongs to that large and indefinite class known as the depressomotors. As to the individual members employed, the effect of amyl nitrite taken as a standard is to increase the frequency of the pulse and rapidly to diminish the blood-pressure. All the members of the vasodilator group have essentially the same action on the circulation as amyl nitrite, varying slightly because of particular minor characteristics of the individual drugs. The individual selection of the particular drug to be employed in a given case will depend upon the character of the case, the urgency of immediate action, and the effect desired. Before employing any drug of this group, it should be carefully ascertained that the preparation, particularly if a solution, is strictly fresh, as failure to obtain the desired result may be due entirely to the use of an inactive specimen. Tablet preparations are known to vary greatly in strength and should be of standard make. This defect can, according to some observers, be avoided by the employment of fresh chocolate preparations. Sodium nitrite in solution rapidly loses its activity and should not be kept for more than one week. All these drugs may be employed hypodermically when desired, but for continued use they should, if possible, be given by the mouth. Miller has pointed out an interesting clinical fact, that not only may wide variation in the effect occur from day to day, but different drugs of the same group, as nitroglycerin and sodium nitrite, may affect the same individual differently. Vasotonin is a combination of yohimbin and urethane. The use of this preparation has been confined chiefly to Germany, and so far American observers have failed to obtain the uniformly favorable results reported abroad. In view of the dissenting evidence the drug cannot be recommended, and if used at all its effects should be followed with care. As to diuretin, W. H. Hamburger strongly advocates the use of theobromin in this form and finds it very valuable in hypertension and arteriosclerosis of the abdominal vessels, although the effect on the heart is not constant. B. D. C.

Neosalvarsan.—Abr. L. Wolbast, in the *Medical Record* for July 27, presents a preliminary report on neosalvarsan. Neosalvarsan is the name given to the newer and better salvarsan the laboratory number of which, 914, indicates the tenacity and fixity of purpose which predominate in the Frankfurt Institute. His conclusions as to neosalvarsan are, 1. The clinical results are at least as striking as those of salvarsan. 2. The reaction after treatment is nil or very slight with correct technique. 3. Larger doses are more readily tolerated than the salvarsan. 4.

The neutral reaction of the solution in water obviates the use of sodium hydroxide, thus avoiding the possibility of thrombosis. 5. Leakage of neosalvarsan into the tissues seems to be absorbed much more quickly than the salvarsan. 6. Patients feel the inflow of the neosalvarsan solution much more than that of salvarsan, in the form of a sense of burning at the site of the injection. 7. Neosalvarsan has no apparent effect on the eyes, kidneys, heart or lungs. 8. Intravenous injections may be repeated in two or four days. 9. The neutral reaction of neosalvarsan solution lends itself readily to intramuscular medication, which is admittedly more efficacious than the intravenous. 10. The suspension in glycerin is made almost painless by adding a few drops of 1 per cent beta eucaine or alypin solution. 11. The solution of neosalvarsan in distilled water is very painful. B. D. C.

Blood-Pressure.—In the *Archives of Internal Medicine* for August, Harlow Brooks and John H. Carroll report the results of a clinical study of the effects of sleep and rest on blood-pressure. Numerous physiological researches on both man and the lower animals have shown that there is a marked fall in blood-pressure during sleep. Leonard Hill, although admitting that a fall in pressure took place, did not believe that this drop was any greater during sleep than that which has been demonstrated to occur as a result of simple rest combined with the prone posture. Brush and Fayerweather, however, showed definitely that this was not the case, but that the fall was concurrent with sleep and that it was greater than the drop which sometimes, with sleep invariably, takes place simply from rest or lying down. In attempting to apply these observations clinically Brooks and Carroll endeavored to ascertain whether prolonged sleep causes a proportionate lowering of the pressure. Within an ordinary degree at least this does not appear to be the case, and attempts to secure even a temporarily lower twenty-four hour pressure by prolonging or deepening the sleep were apparently without avail. Furthermore they found that little difference existed in the total twenty-four hour pressure whether the patient is confined to bed or is allowed to be up and about. A special series of observations (ten instances) were conducted to determine whether the sleep drop might not be artificially increased in order to secure a lower pressure curve in concrete cases of high pressure. They obtained no results in this direction and in cases in which the drop and curve has been previously determined, by the administration of potassium bromid in a dosage of 120 grains the degree or persistence of the fall was not increased. The same lack of result was shown

when chloral hydrate in a dosage of 50 grains per night was given; the drop and curve were not materially altered. From these and other clinical observations they feel justified in the discouraging conclusion that this sleep drop cannot as yet be utilized therapeutically to lower the blood-pressure and that although its effect in high blood-pressure cases is more marked than that of any drug in medicinal doses it cannot be employed therapeutically. It may, however, be said parenthetically that the more they study this question of blood-pressure, the more they become persuaded toward the conclusion that the often frantic efforts to lower high blood-pressure are perhaps as harmful, if successful, as they are usually futile. B. D. C.

PULMONARY TUBERCULOSIS.*

By W. L. TYLER, *Curdsville.*

Tuberculosis is an infectious disease, caused by the bacillus tuberculosis. The infection is a slow one of indefinite incubation, and after the implantation of the specific germ, it may be weeks, months, or possibly years, before any manifestations of the disease appear.

When the microorganisms become effective by means of a favorable soil, it produces a specific inflammation, characterized by a new formation of tissue either in the form of tubercle or of a diffuse tubercular exudate. These new products undergo further change resulting in caseation and sclerosis; in the former, we may have softening, destruction, encapsulation by means of fibroid envelope or calcification; in the latter a transformation of the tubercle or exudate into a cicatricial fibroid tissue. In fact, these two processes generally go on together, and the course of the disease depends on which is predominant. Nature produces her cure by the overthrow of the caseous tendency, through the stronger fibrous one; and in absolute tuberculous lesions of the lungs, met with at autopsies, a fibroid induration at the apex of the lung, or a caseous nodule encased in fibroid envelop is all that remains of a previous tubercular focus. In the lungs, the most common seat of tuberculosis, and where it is most important clinically, the destructive process caused by the bacillus prepares an inviting medium for other microorganisms, principally the streptococcus, staphylococcus and others.

The secondary or mixed infection gives rise to characteristic symptoms of septic nature, the "hectic fever." Although there is a difference of opinion regarding the role played by the introduction into tubercular tissues of other microorganisms, still the view is gen-

erally held that the mixed infection is the immediate cause of fatal results in some cases. Whether or not a pure tubercular infection, without the presence of other bacteria, is accompanied by fever or other constitutional disturbances may be a debatable question. As however the tuberculosis extends from the primary infection, and reaches a certain time period, it is likewise probable it is accompanied by fever—the initial fever. Further evidence of this is the fact that a rise of temperature follows the injection of tuberculin, if there is any tubercular focus in the body; and furthermore high fever is a constant symptom of miliary tuberculosis, which is a pure tubercle bacillus infection. I think it is later in the disease that we have the so-called "hectic fever" of mixed infection. Infection very rarely occurs from transitory exposure to the bacillus or in the open air. It is by a continued and oft repeated exposure, as in infected houses or workshops, that the disease is most frequently contracted. Fliick has well named tuberculosis a "house disease." The observation is common of one member of the household becoming tuberculous, after long confinement in the house, breathing bacillus-laden atmosphere, while caring for another member suffering from the disease.

The cause of these numerous cases in the same family, was formerly ascribed to inheritance—we now know it is infection. But with continued exposure to the infection, not every one exposed to the disease will develop it; there must be at the same time a receptive state which may be the result of an inherited or acquired susceptibility—more frequently the latter.

Genuine inheritance of tuberculosis is extremely rare if it occurs at all (although late observations would seem to indicate that the tubercle bacillus is found in the placenta of tubercular women) and we can only ascribe to a tuberculous ancestry a predisposition to the disease or a favorable soil.

Whatever causes (and they are numerous) produce a decline from normal standard of health and depress the resisting power of man, work toward the preparation of a favorable soil and it is the cooperation of the seed and the "good soil" which results in the production of tuberculosis. In the endeavor to convert a receptive organism into a resistant one lies the whole theory of the present "hygienic dietetic treatment." The greatest source of infection is from human beings, suffering from tuberculosis, and especially the sputum from the pulmonary form. The tubercle bacilli gain access to the body through (a) the respiratory tract by inhalation; (b) the alimentary canal by ingestion; (c) and rarely the skin by inoculation.

* Read before the Daviess County Medical Society.

There is still considerable difference of opinion as to the relative frequency of the inhalation and ingestion modes of infection, but the former, the respiratory route, is generally regarded as the most frequent and hence the aerogenic source of infection is to be regarded as the most common and our prophylactic measures should be directed towards the dust which may hold in suspension the bacillus.

It must be remembered that this infected dust may also be deposited on articles of food and the germ by this means enter the body by ingestion.

In my opinion the housefly plays no insignificant part in disseminating tuberculosis. Andre has shown that flies fed on sputum from tubercular patients, evacuate considerable quantities of bacilli in their excretions, appearing six hours after the ingestion of the sputum and some are found as long as five days later.

He also found that food polluted by flies that had been fed on sputum contained infective bacilli and produced tuberculosis in guinea pigs. Once in the body the distribution of the bacilli from the original focus takes place by means of the blood and lymphatics.

Some noted phthisiologists have shown that in many cases the infection reaches the lungs through the tonsils, either from without or through the blood stream, as in acute miliary tuberculosis. When the tonsils are tubercular, the cervical glands become secondarily involved through the lymphatics coming from these organs. Again the lungs may become infected through a primary infection in the bronchial or mesenteric glands. Wherever the primary may have been or however it may have occurred, in the greater number of cases the lungs sooner or later become involved. There are many influences both psychic and physical, acting from within the body and through the environment, which predispose one to tuberculosis. Some of which are: Vicious personal habits such as overwork, underfeeding, lack of sunshine and fresh air, insufficient sleep, the abuse of alcohol and tobacco; certain previous diseases, as diabetes, pneumonia, recurrent bronchitis, measles, whooping cough, la grippe and others; unsanitary surroundings, density of population, unwholesome occupations as the dusty trades; a climate permitting limited out-door life.

The onset of pulmonary tuberculosis is often such as to mislead the physician. In some cases there is no cough but a rise of evening temperature; another type of onset is found in those cases which present pleural effusion; in some cases the earliest symptoms are laryngeal; in another type of cases the earliest symptom is the spitting of blood; a symptom in nearly all cases is loss of flesh and strength.

The extension of the inflammation to the visceral layer of the pleura causes severe pain in the chest. Sweating occurs at some time in well developed cases; sometimes dyspnea on slight exertion is a marked symptom.

It must be remembered, however, that the severity of the symptoms of all kinds varies to an extraordinary degree in different cases and at different times in the same case.

The above mentioned symptoms are complained of by the patient and can readily be observed by the physician; but in arriving at a diagnosis we may have such additional information as may be obtained from physical signs. With all the evidences heretofore mentioned, we may be mistaken or in doubt regarding the diagnosis, as such evidence might well be considered circumstantial. The microscopic finding of bacilli gives positive diagnosis, failing to find the tubercle bacillus in the sputum is not always positive evidence of the patient not having a tubercular focus. However the microscope is the most practical means of making a diagnosis of pulmonary tuberculosis. Tuberculin is claimed to give a positive reaction in nearly every case of tuberculosis. (I must admit I have had no experience with tuberculin). I have tried tuberculin ointment for Moro's test which has given satisfactory results in some cases and disappointed me in others.

Two lines of attack have been employed in the treatment of tuberculosis; first that directed towards the infection itself, the tubercle bacillus, either by means of specifics or antiseptics, or the establishment of immunity by the use of antitoxins or serum; second, that directed towards the individual to restore the normal resistance of the organisms, the so-called hygienic diatetic treatment, or open air treatment. The first method has never been a success and the future can only decide whether it ever will be; the second one has been eminently so and is the established method of the day. It is not only the natural course of treatment from the cause of the disease but abundance of experience has proven its efficacy.

Since the treatment is of the individual and not directly the disease, we should use only such means as will increase the vital powers and render them rebellious to the bacterial invasion. The ever present anemia in these patients demands the careful administration of such tonics as, iron, quinine, strychnine, and arsenic in various forms. The syrup hypophosphites has its advocates. Elixir of glycerophosphates seems beneficial in some cases. I have found the emulsion of petroleum of apparent benefit in some cases, but have found it necessary to discontinue it in others. Cod-liver oil is so nauseous that I doubt its virtue. I think that the use of creosote with

the idea that it is beneficial for pulmonary tuberculosis is based upon an utterly erroneous view of the disease, as well as the action of the drug. My observation is, that creosote tends to disturb the digestion, and anything which disturbs the digestion and assimilation of food, diminishes the vital powers of the patient and thereby diminishes his prospects of recovery. I want to go on record as believing that creosote is absolutely detrimental to tubercular patients. I caution my patients to continue to take no drug which they find interferes with their appetite or digestion. I feel quite sure that the number of unfortunate consumptives, whose struggle with this disease has been lost through disorders of digestion, arising from the injudicious administration of drugs, is not comforting to contemplate. The disturbance of digestion which inevitably arises, may be benefited by the administration of such drugs as pepsin, pancreatin, takadiastase or Hcl.

I think an occasional purge assists in eliminating the accumulated toxins. In my brief reference to the drug treatment of tuberculosis, I shall not refer to the treatment of the complications, but shall state that the complications should be judiciously met as they arise. I shall discuss the drug treatment by saying, that I sincerely believe that whenever a physician in the treatment of pulmonary tuberculosis is tempted to employ a drug, the question of its influence on the stomach and digestion should be carefully decided before the administration of the drug. Tuberculin was for a time discarded in the treatment of tuberculosis, but recently its merits have been lauded by some where judiciously administered in well selected cases. Artificial pneumothorax in treatment for pulmonary tuberculosis, has recently given some flattering results. But it is the open air and carefully selected diet which have given the most brilliant results.

My experience has been absolutely in treating tuberculosis in the private home. Too much praise can not be given the Sanatoria treatment, but I know that good results can be obtained in private homes; and this is gratifying since the majority of cases must be treated at home.

The three cardinal points to be remembered in the treatment of tuberculosis anywhere, are, pure air, food and rest, and the success in our treatment comes from the skill and persistence in their use. The open air treatment can not be carried out in the private home as we usually find them constructed, but I have found that a small investment will obtain the facilities for securing plenty of fresh air. In some instances, I have screened a porch, others used a tent, and on others built a shack with screened walls, having curtains to draw

as needed. The open air treatment consists essentially in the constant and continuous exposure of the patient to pure air. Nine-tenths of consumptives have lived comparatively an indoor life and the radical change to the outdoor life is almost appalling to them. It requires persistent and vigorous effort to keep them up to it. They are apprehensive of taking cold, they fear they have not sufficient strength to endure the exposure, but the physician must be firm and meet such statements positively. When once the outdoor habit is established, enthusiasm takes the place of fear. The sense of well-being caused by the stimulating effect of constant hyperaeration is so keen and its evidence of beneficial effect on the cough, the subsidence of expectation and fever and the improvement of appetite is usually so apparent that the patient will continue to take his open air treatment in all sorts of weather. In a time not very remote, climate was considered to be the most potent factor in the treatment of tuberculosis. With regard to the exact place, climate should hold in the therapy of tuberculosis, there exists a variety of opinions. One extreme values climate as a means of obtaining fresh air, the other extreme looks upon climate as a fundamental principle in the treatment. I feel quite sure that the beneficial results of climate have been overestimated and that by some too much stress is now placed on climate.

Accepting the fact that tuberculosis in its curable stage is susceptible of arrest or cure in almost any climate, where pure air is obtainable, I consider that climate is beneficial to the extent that it permits the application of the open air treatment.

It has been wisely said that proper nourishment is the foundation and the cornerstone of tubercular treatment. No change of climate nor the open air life, will bring success in the treatment unless the nourishment of the patient is such that the past loss be made up and the body weight gained. It is a fixed fact that the consumptive who can not or will not take a liberal amount of nutritious food is doomed to die. While it is very essential to feed in liberal amounts, I think we can make the mistake of overfeeding. I feel quite sure that most all consumptives, if encouraged to do so, can and will take more food than individuals in health. Also I know that I have seen my patients suffer the ill effects of overfeeding and have seen the digestive disturbances disappear and the appetite return only when the food had been reduced in quantity.

Each patient is a law unto himself and so it is we can establish any fixed quantity of diet. We should feed just that quantity of food as is digested and assimilated! Any ex-

cess beyond this only weakens the powers of digestion, and assimilation and interferes with normal functional activity, by an excess of excretory products.

What to eat is to some extent a mooted question. But the experience of the most competent men is that each patient is a law unto himself in this respect also. It is generally accepted that the diet of meat, milk and eggs is the most wholesome and nutritious but an effort to give these articles exclusively is likely to fail, from the same fact that an individual in health would rebel against the same articles of food given at each meal for consecutive days. While meat, eggs and milk are the principle articles of diet, I am sure the patient can consume more of these in the given time of treatment by adding judiciously a variety of well-cooked and appetizing foods, consisting of vegetables, bread, butter, cereals, cheese, nuts, fruits. Of course, meals should begin at exact times of the day, but the frequency of the feeding will necessarily vary with the patient.

In the treatment of pulmonary tuberculosis, it is now agreed that rest is very beneficial. Cases running fever should be kept at rest. In the afebrile cases, much rest is also insisted upon, in cases with low vitality and those who have lost much flesh. I think it wise to put all patients to rest for first few weeks. What is the treatment for local tubercular infections, such as hip-joint and Potts' disease? The answer is rest. So it is, the diseased lung should be put to rest so far as it can be.

When one of the lungs is affected with tuberculosis, even if the disease is limited to the apex, the movement of the diaphragm on the affected side is diminished; and again when the lung becomes tuberculous, adhesions are formed in many cases between the lung and the pleura.

By these means, nature is immobilizing, apparently applying a splint and securing rest of the diseased part, just the same as we do in the treatment of hip-joint and Potts' disease. Since the primary effort of nature is to secure rest of the diseased part, we must necessarily do all we can to assist nature, by demanding rest of our patients, especially during the progressive stage of the disease. In no other common disease, is it so much in the power of the physician to render service to the human family as in the prevention and treatment of tuberculosis. At the beginning certain general facts must be recognized as governing principles in the management of the disease.

1st. That there is no specific remedy for tuberculosis as yet known.

2nd. That there is no antiseptic which materially influences the local infection.

3rd. That the whole treatment is an indirect one—a treatment of the individual and not the disease consequently the treatment must be strenuous and an exacting one, both on the part of the physician and the patient.

No single element, says Cornet, neither air, food, hydrotherapy, nor medicine promises us any prospect of success; only the combined fulfillment of all the physiologic and hygienic conditions of life to the smallest detail, gives us a prospect of success. In order to secure the cooperation of the patient he must be truthfully told of his condition, and its dangers as well as the hopeless outlook from treatment if he disobeys his physician. The personality of the physician counts for more in the treatment of this disease than any other. Firmness, tact, kindness, patience, insistence and cheerfulness are qualities of supreme importance in the physician who shall treat pulmonary tuberculosis with the highest measure of success.

When we realize that 15% of the tombstones in our cemeteries, stand monumental to the ravages of tuberculosis, we readily see we are confronted every hour with an enemy more treacherous and destructive than war. The realization that tuberculosis, the most prevalent disease, is preventable and curable, should arouse every man in the medical profession to his responsibility and duty in the warfare against this, the most disastrous of all diseases.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Nonofficial Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

REFORM IN MEDICINES.

RADIOACTIVE SUBSTANCES IN THERAPY.—From a discussion on the therapeutic value of radioactive preparations at the German Congress of Internal Medicine in April of this year, the conclusion seems to be justified that very large doses of the emanations or of the thorium X solutions are necessary to secure therapeutic results and in these cases the therapeutic results appear to be separated from the toxic action by a very narrow margin. It is evident, therefore, that the use of these substances is still in the experimental stage, that little if any effect is to be expected from preparations on the market, especially as they contain only extremely minute doses which, although probably safe, are probably also worthless.

MEDICAL MEETINGS AS ADVERTISING MEDIUMS.—The promotion of a proprietary nostrum by means of papers read before a medical meeting has gone out of vogue in this country. But while conditions have improved here, they seem to have grown worse in Germany. Now, however, it appears that a halt will be called before long. Recently Dr. Bernheim, of Paris, who is much interested in the exploitation of a new "consumption cure" read a paper before the German Congress for Internal Medicine. Later this paper was reprinted and distributed by the promoters of dioradin. Included with this reprint were testimonials which originally were not a part of the paper. The reprint bore the imprint "German Congress for Internal Medicine" and thus the society was made to lend official sanction to the testimonials. In view of this a protest has been issued by the presiding officer, Professor Penzoldt. This protest is evidence that the German medical profession is awakened to the wretched conditions which have developed in that country in connection with the exploitation of proprietary medicines.—*Jour. A. M. A.* Aug. 17, 1912, p. 549.

AN OPPORTUNITY FOR THE PHARMACIST.—Although the pharmacist can do much toward the advance of medicine and also toward the improvement of the public health, his commercial tendencies have to a large extent made him lose sight of his opportunity. While, in particular, the tendencies of the National Association of Retail Druggists towards the perpetuation and extension of the patent medicine and the nostrum business have not been a credit to pharmacy, *N. A. R. D. Notes*, the official organ of the N. A. R. D. has start-

ed a public health propaganda department in which the druggist is urged to protect the public by giving advice as to the seriousness of various disease and the need of their treatment by trained physicians. When it is considered that a large number of people go to their druggist for advice or treatment for ailments of all kinds, the opportunity which is in the hands of the pharmacist will be appreciated.—*Jour. A. M. A.*, Aug. 17, 1912, p. 560.

MARJORIE HAMILTON OBESITY CURE AFTERMATH.—Following the exposure of the Marjorie Hamilton Obesity Cure, *Jour. A. M. A.* March 16, 1912, p. 798) the United States postal authorities took a hand and on June 7, 1912, W. C. Cunningham and his wife, Marjorie Hamilton Cunningham, were indicted by the federal grand jury and placed under arrest for fraudulent use of the mails. Although, since the Marjorie Hamilton business was exposed, Cunningham has branched out into a new mail order fake line, a "quick wrinkle remover" introduced by "Princess Tokio" the Denver papers now announce that he will withdraw from business and confine himself to the European field—where frauds of this sort are less liable to be molested.—*Jour. A. M. A.*, Aug. 17, 1912, p. 561.

TYREE'S ANTISEPTIC POWDER.—For years Tyree's Antiseptic Powder was advertised to the medical profession with claims that were unwarranted as to both composition and therapeutic effect. Analyses show that the preparation was essentially nothing but a simple mixture of sulphate of zinc and boric acid. The medical profession having prescribed the nostrum, the original package scheme did the rest and now Tyree's Antiseptic Powder goes to the public direct. It is now advertised in newspapers as "Ideal for douche," "Best preventative known," etc. That a nostrum of this sort should go to the public is not surprising but that it should have reached the public through the instrumentality of the medical profession is a serious reflection on the judgment of physicians. That the exploiters of this nostrum no longer find it profitable to use medical journals as a means of needs use the more expensive newspaper advertising, is cause for optimism. It means that physicians are no longer prescribing indiscriminately, proprietary products and that they are refusing to be, what they have been in the past, the unpaid distributing agents for nostrum venders.—*Jour. A. M. A.*, Aug. 24, 1912, p. 666.

THE REPORT.

The long expected report of the State Inspector and Examiner as to the affairs of the State Board of Health, which is simply a continuation of the Herrington fight of last winter, has been published. From a more or less cursory perusal of the forty-three pages of the report we would gather that the Inspector does not cordially commend the work of the Board. We feel sure that it will always be a matter of great regret to the distinguished members of the State Board of Health, many of whom have long since been numbered among Kentucky's honored dead, that this young Moses did not become of age in 1878 so that he might have been its law-giver in the years of travail and poverty during which it really needed one. Fortunately for the health of the people, however, during that trying period it was guided by constructive rather than destructive statesmen and public officials. Through all these years it has had the special approval of Governors James B. McCreary, Luke P. Blackburn, J. Procter Knott, Simon Bolivar Buckner, John Young Brown, W. O. Bradley, J. C. W. Beckham, and not a dollar of its appropriations could ever have been drawn without the explicit official approval of the long line of distinguished auditors from General Fayette Hewitt to Henry M. Bosworth. The State Board of Health has very wisely ordered the full report published in its *Bulletin* and widely distributed among the citizens of the State. As the *Bulletin* reaches every subscriber of the JOURNAL it will save us the necessity for publishing it, and we feel sure that we are violating no confidence when we state that its publication will carry the refutation of every material statement with it.

It is only necessary for us to say that the

State Inspector and Examiner was only in the offices of the Board for an hour, and never saw the Bacteriological and Hookworm Laboratories, which he recommends to be placed in the same room with the Water Analysis Laboratory because it could thus be conducted more economically!

That the report has been approved by some advertising quacks in Louisville, who are being prosecuted under the Medical Practice Act, and by the late Mr. Herrington, et al., of Madison County, will carry sufficient condemnation to the informed profession of Kentucky to obviate the necessity for much other proof. We feel sure that the State Board of Health has the confidence and support of every patriotic Kentuckian, and we are not entirely certain but that one of the strongest points in its favor is the enemies it has made.

THE LOUISVILLE MEETING.

It hardly seems possible that another meeting of the State Medical Association can ever be held under more favorable auspices or more successfully than the recently adjourned one in Louisville. The attendance breaks our record but this was the smallest element in the success of the meeting. An excellent scientific program had been arranged and while it was too crowded to enable the membership to enjoy the usual amount of discussions, which is such an important part of the scientific work, it was so splendidly managed by our able President, that one was hardly aware that it was hurried at all. The scientific and commercial exhibits were far the best we have ever had. We feel that we are not exaggerating when we say that every physician who failed to see the exhibit of Dr. Martin H. Fischer, of Cincinnati, on Experimental Nephritis and that of Dr. J. H. Hendren, of Cary, on Pellagra, missed a post-graduate

course of the highest practical value. As equally noteworthy, were the exhibits of Drs. Vernon Robins and Leo Bloch, of Louisville, on Cerebro-Spinal Meningitis and a pathological exhibit by Dr. Leon K. Bakdauf, of the University of Louisville.

The Committee had a difficult task in deciding which one of the commercial exhibits was of the highest educational value to the general practitioner, but after much deliberation, finally awarded the prize to H. M. Alexander & Company, of Marietta, Pennsylvania, for an exhibit of antitoxins.

The banquet was splendid. The food was both excellent and hot and the fact that it was served simultaneously to more than five-hundred physicians, was a credit not only to the Committee which arranged it, but to the Messrs. Seelbach, who managed it. The annual oration, delivered by the President-Elect of the American Medical Association, Dr. J. A. Witherspoon, of Nashville, was all that could be expected from this able and scholarly physician. Especially noteworthy, was the splendid effect on everybody present of holding the meeting in the magnificent temple, of which Dr. E. L. Powell, is the worthy pastor. The symposium on "Health," arranged through the efforts of Dr. Heizer, and that on "Pellagra," by Dr. Sprague, were surpassingly interesting. To any but the most careful observer this meeting would seem to be the highest mark of medical organization in Kentucky, with more than one-third of the active physicians in the State present. We may possibly never exceed the proportional attendance, but it is important that in this glorification we all pause to remember that medical organization has not accomplished its purpose until every portion of every county, however remote, has access to a thoroughly competent physician, who can tell its people not only how to get well from disease but how to escape from all that large class which we now know is preventable.

ENFORCING THE MEDICAL PRACTICE LAW.

The quacks and illegal practitioners of medicine have been taking great joy to themselves because of a recent decision of the State Inspector and Examiner that the State Board of Health could not use any of its funds for the employment of attorneys in the prosecution of offenders against the Medical Practice Act. Their joy will be short-lived, however, as the Kentucky State Medical Association, at its recent annual session, unanimously appropriated an amount not to exceed \$750.00, to be used by its Council in cooperation with the State Board of Health in the enforcement of the law. Contracts have already been made

whereby evidence has been secured against several notorious offenders, who have recently come into the State and we feel sure that the entire profession of Kentucky will be glad to uphold the efforts of the Council to enforce this law, which is second to none for its beneficent effect in protecting those of our people who are sick or afflicted from such vampires as prey upon them in other states. This use of the funds of the Kentucky State Medical Association will, we trust, be temporary, as all the officials concerned have agreed to assist in securing such a modification of the law by the next General Assembly as will enable us to continue our work without any technical violation of the rulings of the subordinate officials in Frankfort.

SALE OF OPIUM BY PHYSICIANS PROHIBITED.

We are publishing as a part of this editorial a letter from the State Board of Pharmacy, which is self-explanatory. We are sure it is only necessary to call the attention of the profession to this matter to stop the abuse, about which Dr. Gayle complains. THE JOURNAL trusts it will not be necessary to prosecute any Kentucky physicians for violation of law which we all helped to put on the statute book.

DEAR DOCTOR McCORMACK:

Among the most serious of a multitude of difficulties which this Board is having in the enforcement of the law passed by the last legislature prohibiting the sale of opium, its derivatives or their salts, except upon the original prescription of the physician, is one which you can no doubt do much to eliminate, viz.: the tendency upon the part of a good many physicians to supply the public with these drugs when the druggist has refused to furnish them.

This tendency, amounting in many instances to an actual custom, is probably due largely to some confusion in the minds of certain physicians as to their rights under the law, and who fail to discriminate between the act of dispensing drugs to his own patients (a right which no one would attempt to deny or desire to interfere with), and the practice of supplying a drug to the public (a practice which no one can defend).

Time and time again have our inspector and his workers—total strangers—purchased in the physician's office morphine and other drugs by simply asking for them, and under conditions and circumstances which could in no way uphold the physician in the contention that he was acting within his right to dispense drugs to his own patients.

Another thing we have found which is, if possible, more pernicious. A number of phy-

sicians have been detected apparently making a business of indiscriminately writing prescriptions for cocaine in quantities to suit the applicant—always an habitual user—charging for this service sums ranging from 25 to 50 cents! Of course druggists can always be found sufficiently devoid of the sense of moral obligation to unhesitatingly fill such prescriptions.

The laws controlling and regulating the sale of the habit-forming drugs cannot be made effective except through the united and co-operative efforts of the pharmacist and the physician. Will you not use your influence through your JOURNAL, and otherwise in bringing this about?

Very truly,
J. W. GAYLE, Secretary.

THE DISTRIBUTION OF BIOLOGICAL PRODUCTS UNDER THE DIRECTION OF THE KENTUCKY STATE BOARD OF HEALTH.

The physicians of the State are reminded that antitoxins, bacterins, vaccines and emulsive serums, which may be required for the treatment of indigent persons, can be secured at the expense of the several counties in the State. The local boards of health with the consent of their county judge have power under the law to spend money for this purpose.

In order to make readily available to the Health Officers in all sections of the State a complete and reliable line of biological products, at best Board of Health prices, the State Board of Health has made special arrangements with H. K. Mulford Company, Philadelphia, for the distribution of their well-known and standard line. These biologicals are dispensed under special Board of Health label, and a supply is carried in the office of the State Board of Health at all times.

Requests for material should therefore be sent to the State Bacteriologist, State Board of Health, Bowling Green, Ky. Later the Board of Health reports to the H. K. Mulford Company the amount of goods dispensed and the H. K. Mulford Company sends a bill and collects for the same direct. Owing to the very special prices extended, it is understood that prompt payment is required.

Following is a list of the more important biological products, together with their indicated use, and the special prices at which they will be furnished to the local health officials of Kentucky, for the treatment of indigent persons, as provided by this special arrangement.

TETANUS ANTITOXIN (HUMAN).

Each dose in an aseptic, glass syringe, ready for immediate injection,
1500 units (immunizing dose)...\$1.50

3000 units (therapeutic dose)... 2.55
5000 units (therapeutic dose)... 3.60

ANTI-DYSENTERIC SERUM.

For summer diarrhea and dysentery
In syringes of 10 c.c. each,\$1.20

ANTI-MENINGITIS SERUM (HUMAN).

In packages containing two syringes of 15 c.c. each, including special needle for intraspinal injection,

Per package\$3.00

ANTI-STREPTOCOCCIC SERUM.

In syringes of 10 c.c. each\$.90

In packages containing 2 syringes of 10 c.c. each, per package.... 1.80

RABIES VACCINE (PASTEUR METHOD).

Per complete treatment of 25 doses, including outfit, so that new sterile syringe and needle can be used for injection of each dose\$35.00

SMALL-POX VACCINE VIRUS (GLYCERINIZED).

Glass points or capillary tubes,
per case of 10 vaccinations\$.65

COLI-BACTERIN.

Indications: Cystitis; fistula in ano; catarrhal jaundice; local infections caused by bacillus coli. Furnished in aseptic, glass syringes as follows:

Syringe A contains 50 million killed bacteria,
Syringe B contains 100 million killed bacteria,
Syringe C contains 200 million killed bacteria,
Syringe D contains 400 million killed bacteria,
Per package of 4 syringes, A, B,

C, D, as above\$1.20

MENINGO-BACTERIN.

Indications: For immunization against spinal meningitis. Furnished in aseptic, glass syringes as follows:

First dose contains 500 million killed bacteria,
Second dose contains 1000 million killed bac.
Third dose contains 1000 million killed bac.

Per package containing 3 syringes as above, comprising one complete immunization\$.90

Board of Health size package containing 30 doses, in separate ampuls, comprising ten complete immunizations 2.10

NEISSER-BACTERIN MIXED.

Furnished in aseptic glass syringes as follows:

Each syringe contains	A	B	C	D
Etaphylococcus aureus	100	200	400	800 mil.
Staphylococcus aureus	100	200	400	800 mil.
Streptococci	50	100	200	400 mil.
B. coli	50	100	200	400 mil.
Pseudo-Diphtheria	50	100	200	400 mil.
Gonococci	50	100	200	400 mil.

Per package of 4 syringes, as above\$1.20

SCARLATINA-BACTERIN (IMMUNIZING).

Indications: For immunizing against scarlet fever. Furnished in aseptic, glass syringes as follows:

First dose contains 250 million killed streptococci,

Second dose contains 500 million killed streptococci,

Third dose contains 1000 million killed streptococci.

Per package of 3 syringes, comprising one complete immunization\$.90

STAPHYLO-BACTERIN.

Indications: Furunculosis, acute and chronic; acne; sycosis. Furnished in aseptic, glass syringes as follows:

Syringe A contains 250 million killed bacteria,

Syringe B contains 500 million killed bacteria,

Syringe C contains 1000 million killed bac.

Syringe D contains 2000 million killed bac.

Per package of 4 syringes, A. B.

C, D, as above\$1.20

STAPHYLO-ACNE-BACTERIN.

Indications: Acute and chronic acne caused by mixed infection. Furnished in aseptic, glass syringes as follows:

Each syr. contains A B C D
Staphylococci250 500 1000 2000 mil.
Acne bacilli..... 25 50 100 200 mil.

Per package of 4 syringes, A. B.

C, D, as above\$1.20

STAPHYLO-BACTERIN MIXED.

Indications: Mixed infections, as fistulous sinuses, etc. Useful for immunization before abdominal operations. Furnished in aseptic, glass syringes as follows:

Each syringe contains A B C D
Staphylococci 25 50 100 200 mil.
Staphylococci100 200 400 800 mil.

B. coli 50 100 200 400 mil.

Per package of 4 syringes, A. B.

C, D, as above\$1.20

TYPHO-BACTERIN (IMMUNIZING).

Indications: For immunization against typhoid fever. Furnished in aseptic, glass syringes as follows:

First dose contains 500 million killed bacteria.

Second dose contains 1000 million killed bac.

Third dose contains 1000 million killed bac.

Per package of 3 syringes, comprising one complete immunization\$.90

Board of Health size package containing 30 doses, in separate ampuls, or 10 complete immunizations 2.10

TYPHO-BACTERIN MIXED.

Indications: For immunization against typhoid fever and conditions diagnosed as typhoid but caused by the paratyphoid bacilli

(*Bacillus typhosus*, *bacillus para-typhosus* "A" and *bacillus paratyphosus* "B"). Furnished in aseptic, glass syringes as follows:

	Syringe	1	2	3
<i>Bacillus typhosus</i>		500	1000	1000 mil.
B. Paratyphosus "A".....		250	500	500 mil.
B. Paratyphosus "B".....		250	500	500 mil.

Per package of 3 syringes, as above, comprising one complete immunization\$.90

Board of Health size package containing 30 doses in separate ampuls, or 10 complete immunizations 2.10

GENIUS AND HAIR COLOR.

Chas. Kassel, in the *Popular Science Monthly*, for September, propounds to himself and investigates the question as to whether there is any relation between those wonderful individuals we call geniuses and the color of their hair. We are all interested in hair, some because of the desire to preserve the suprabundance that they have, others because of the mournful lack of it, and the need of a teepee. Hair is a remnant of the coarse fur that once covered the body of the human animal, which in the long course of evolution has withdrawn at last, after a losing battle with time, to its invincible retreat and stronghold, upon the head. "This relic of beast life grew with the process of the sun, into a thing of use and meaning, a mark of race, an emblem of rank, a symbol of religion, and lastly, but chief of all, into an adornment of surpassing beauty, affording to cupid, a most potent weapon in his merry warfare against the sons and daughters of men." Kassel reviews the place of hair in the religious life of the race; among the Greeks and Romans, it was worn until the fourteenth year, then severed and dedicated to the River God. He notes that in the Roman Catholic and Hindu Churches, throughout all the ancient world, the tonsor in one form or another was a sacred right, true like, of the vestal virgin, Roman Catholic Nuns and Monks, etc.

Fancy has sought to attach to it deeper meanings, thus in all ages stiff and wiry hair has been deemed a sign of dishonesty or low birth, while softly clustering curls, we have ever been prone to associate with gentleness and innocence. Characteristics of the hair in all forms, one of the leading tests of nationality, but there is a fairly well marked difference between the hair of the lower and that of the higher races; thus, black, straight and closely spiral formed hair, usually marked

people low in the scale of intelligence, while among the loftier races, straw colored, chestnut hair, are usually found. In the coarseness of the hair, the lower peoples probably betray their greater nearness in point of development to the animal ancestor of man, since the crowning hair of the Anthropoid brute, the Chimpanzee, Gorilla, etc., is stiff and bristly, generally of a reddish tinge. Among these brutes, no instances of fair hair or blue or gray eyes is known. In nearly all countries, popular snipersation has looked askance at red hair; yellow hair has been conspicuous with talent or deep character, brown or chestnut hair, constancy of purpose, autumn and golden, where the hair is soft, is linked in folk-lore with great steadiness of purpose, and unfaltering loyalty in love. Black hair is greatest among criminals, says Havelock Ellis, although the beards of criminals are usually scanty, while Morro has observed a considerable proportion of woolly haired criminals. Criminal women usually have a remarkable abundance of hair, and it often forms their most characteristic physical feature, accompanied by an unusual development of fine hair on the face and body. The structure of the hair is most interesting among men of genius. The poet's ringlets seemed to represent a distinct fact in biography, and are of marked softness, but fullness seems likewise a frequent accompaniment of artistic and literary genius, the abundant hair of musicians as observed upon the concert platform, will in this connection suggest itself to the reader. The author concludes as follows. "Beyond this, it may be safe, so far to generalize as to hair color that individuals of artistic or literary genius in general possess wavy or curly hair, and that even in a case of genius, it is not amiss to look for the coarse organization where the hair is coarse and stiff. If, moreover, our data may be relied upon, red and yellow hair rarely accompany genius." Kassel has been making some interesting studies of genius, and he well remarks "it is now time that more men should be studying as a part of social evolution, and that methods of exact and statistical science, just as this is being done as regards the criminal, and assuredly genius has no lesser claim upon the time and talents of our workers.

CURRAN POPE.

SCIENTIFIC EDITORIALS.

DESTRUCTION OF BLADDER TUMORS BY THE OUDIN, OR HIGH-FREQUENCY CURRENT.

(FULGERATION).

According to statistics, radical surgery saves life in at least 20% of the patients with benign growths, and in 4 to 6% of the patients with malignant neoplasms.

Benign tumors kill by repeated hemorrhages, producing profound anaemia, which so rapidly reduces the patient's vitality; this accompanied by secondary conditions, such as cystitis, renal infection and sepsis. And when the growth becomes malignant, which is never known—as Alberran has expressed it "all vesical tumors are malignant or, are likely to become so."

Surgery offers four types of radical operations, namely:

I. *Intra-vesical excision.* (Only applicable to small papillomata). Nitze claims admirable results through his operating cystoscope in eighty cases. No operative deaths. Seven recoveries.

II. *Excision, after cystotomy.*

III. *Resection of the bladder.* (Necessary in every sessile and infiltrating growth of the bladder-wall).

IV. *Total extirpation of the bladder.*

Fulgeration has been used by many dermatologists for the destruction of skin-growths for a number of years. Edwin Beer of New York was the first to conceive the idea of applying this method of treatment to growths within the urinary bladder, but he was baffled when told by expert electrical manufacturers that it was impossible to obtain results with high-frequency currents through a water medium; as an air-gap was absolutely necessary. His experimental work was confined to the removal of skin-warts through a water medium, and he was soon convinced of the efficacy of its therapeutic value—despite the absence of an air-gap.

Early in 1910 Beer reported his results in two cases of bladder tumors treated with the Oudin, or single pole high-frequency current. Then Edward Keyes, Jr., reports five cases in *American Journal of Surgery*, July, 1910, treated with high-frequency current, but with the D'Arsonval, or double pole. Later, Keyes reports twelve cases treated with the Oudin current, and frankly admits its superior efficacy to the D'Arsonval current.—(*Inter-State Medical Journal*, Oct. 1911).

Within the last two years, many prominent European and American urologists have given the fulgeration method a fair trial, and report most favorably; some including multiple and

extensive growths which were thought to be inoperable.

While in Chicago last September, I saw a case of multiple papilloma of the bladder under fulguration treatment by L. W. Bremerman. At this stage there were only a few remaining growths, and many scars were plainly visible on the vesical mucosa, showing where papillomata had been removed. Dr. Bremerman told me that when he first saw the patient, almost the entire bladder-wall was covered with papillary excrescences, and that a radical operation, almost amounting to a total cystectomy.

The case that I shall report is as follows:

Mrs. B., aged 36. Bladder symptoms four years, with frequent attacks of haematuria. She returned from the hospital a few weeks previously, where she had undergone a curettement for her trouble. She was weak, anaemic and septic; much fatigued by frequent and painful urination, and was compelled to lie flat of her back during each effort of voiding, as she claimed there was "a something" that would press against the bladder-neck and completely block the urinary passage, if she attempted to void her urine in the sitting posture. The urine was foul, putrid and very offensive.

CYSTOSCOPY.

Bladder capacity, 4 ounces. Bladder contained much putrid and necrotic debris, and only by prolonged flushing could I get the bladder clear enough for a satisfactory examination. However, the cystoscope was introduced, and owing to the cloudy medium, all that could be seen, were masses of phosphatic debris apparently clinging to the bladder wall, and one large mass supposed to be a calculus. The trigone looked eroded and slimy, with some evidence of ulceration.

The bladder was subsequently irrigated for several days with a solution of salicylic acid 1 to 3000, followed immediately with an instillation of one ounce of 20% gomenol oil. The salicylic acid was used to dissolve the phosphatic elements, and to neutralize this putrid alkaline urine; the oil was used for its antiseptic properties, and to soothe the highly inflamed bladder and to facilitate the passing of this grit and sand.

CYSTOSCOPY.

Bladder capacity 6 ounces. This supposed calculus proved to be a phosphatic-capped papilloma. It was elongated, fan-shaped, and attached by a small pedicle, one-half inch anterior to the left ureteral orifice. Clinging to it was a coating of sand, and evidently this growth had been rolling and grinding the trigone causing the excoriation and ulceration, during its effort to block the urethral outlet.

After considering the size and character of

the growth, with its slender pedicle, and mode of attachment, I decided to try fulguration.

TECHNIQUE.

Bladder thoroughly irrigated and filled with sterile water. A direct catheterizing cystoscope introduced; and through one channel was passed a long insulated copper electrode, No 7F., which resembled a ureteral catheter in size and length; the other channel of the cystoscope being capped to prevent any leaking. This electrode being cut off square at the vesical end, while the other end was connected with a Wappler high-frequency machine—the spark-gap in the muffler being set at approximately one-tenth of an inch, and current was thrown into the bladder by means of a foot-switch. The current which lighted the cystoscope was from an eight-cell storage battery; my reason for this was to eliminate any possibility of a short-circuit.

The electrode was advanced and gently pushed against the pedicle, down close to the base of tumor. The current was turned on and continued for thirty seconds. I could readily see the blanching of tissue, accompanied by considerable bubbling of gas—but no sparking could be seen. The current was now turned off for about one minute to allow cooling of the electrode, and prevent the burning of the rubber insulation. The current was again turned on, and the seance lasting for another thirty seconds, which completed the first fulguration.

My patient withstood the ordeal without even a local anesthetic, however she was somewhat fretful and nervous, but did not complain of any pain. A great amount of pain can be produced by having a wide spark-gap, or carelessly allowing the electrode to come in contact with the bladder-wall.

The patient was advised to return to the office in about ten days for another fulguration—but much to my surprise, just before the expiration of the ten days, the husband called me hurriedly over the phone one morning, saying that his wife was passing something from her bladder that looked like a piece of flesh. Soon the husband arrived at my office, bringing the specimen. The tumor measured two and one-half inches in length, one inch in width, and fully three eighths of an inch thick; it was fan-shaped, with somewhat of a suggestion of bifurcation, and partially covered with phosphatic sand; the pedicle was smooth, round and slender, and about the size of a No. 10F bougie. The stump of the pedicle was charred, or carbonized, showing effects of the electrical burn.

Within ten days the bladder had completely cleared up and all symptoms subsided; the urine clear and patient could sleep all night

with comfort, for the first time in nearly four years.

Cystoscopy a month later showed a normal bladder, with the exception of some slight evidence of the stump remaining—this was destroyed by the ouidin current.

Cystoscopy: Five months later; Bladder capacity, comfortable with ten ounces. No evidence of tumor, and only a small scar visible. Entire bladder mucosa normal.

INFANT MORTALITY—ITS CAUSES AND PREVENTION.*

By HENRY ENOS TULEY, Louisville.

Both the profession and the public are awakening to the appalling infant mortality, which for years has gone practically unnoticed. Through ignorance of conditions this slaughter of the innocents has been possible and no efforts have been made to save them to society.

There are so many causes entering into the heavy mortality among infants under five years of age that time will not permit a thorough description of them all in this paper, but I hope that a free discussion of it may bring out all the omitted points with emphasis.

The unpreparedness with which the average graduate in medicine enters upon the practice of midwifery is responsible, I am sure, for the early death or invalidism of many infants which come under his care. I feel that I know whereof I speak on this subject, having taught obstetrics for a number of years. It was always with a feeling of dissatisfaction with existing conditions, which made it impossible to give a more thorough and comprehensive course of instruction at the bedside to the fourth year medical student. This should not only include observations in the progress of the normal puerperium, but instruction in the physiology of the first days of infant life. For the most part the practical experience of the medical graduate consists in viewing from the benches the delivery of two or three women, not seeing these patients or their babies again. A few enterprising ones among the graduating class may care for some of the pauper out-patients in their homes, but they lose much of value in the conduct and care of the case because they have no bedside instruction. Until these conditions are changed and more attention paid to giving practical bedside instruction in obstetrics and pediatrics the average graduate

in medicine will be but little better prepared than the experienced midwife. There are but few specialists in obstetrics, the vast majority of women must be delivered by the general practitioner, hence he should be well trained not only in obstetrics but also in pediatrics, the latter I consider of fully as much importance as the former.

The study of pediatrics should include a thorough course upon the prenatal conditions which might possibly influence the strength of the child after birth. Conditions in the mother which might cause an unusually prolonged labor should also be studied, the proper significance of the fetal heart sounds, and other signs of impending fetal asphyxia, intelligence displayed in the care of the persistent occiput posterior positions, breech and transverse presentations, the more frequent employment of pelvimetry for recognition of pelvic deformities, placenta previa, the indications for and the scientific application of forceps, and when a version or Caesarean section should be advocated.

After birth, too little attention is paid to the infant, exposure is allowed, inspiration atelectasis occurs by failure to extract mucus from the naso-pharynx, the cord is tied too quickly, thus depriving the child of its full share of blood; the eyes are neglected; and it is casually handed to the nurse or an ignorant member of the family without further consideration. By failure to properly supervise the early attentions to the child which include protection from exposure, bathing and care of the navel, pneumonia and infections both general and gastro-intestinal may occur.

In other words, by giving exclusive attention to the mother in this period, equally critical to both mother and child, infantile mortality is begun, which soon adds its store to the sum total of infant mortality.

A study of statistics as related to infantile mortality is of interest, as it proves the above statements. As far back as 1893 it was shown by Eross by studying the statistics of sixteen large European cities and including 1,439,056 children, that ten per cent. of the children born alive die within the first four weeks of life. This mortality was greatest on the first day and diminished each day as the child grew older. Further, congenital debility is given as a cause of deaths in 54 per cent. of infants which died within four weeks after birth. Prof. Irving Fisher in a report to the National Conservation Commission, states that in a series of 100 cases of premature births, 40 were preventable; of 100 children dying of congenital debility 40 might have been saved, and of 100 children dying of venereal diseases 70 might have been saved. These are startling figures and point to the importance of the better training of the gen-

*Read before the Kentucky State Medical Association, Louisville, Tuesday, October 29, 1912.

eral practitioner in pediatrics both prenatal and immediately after birth. Davis* in a recent article calls attention to a few of the potent causes of premature birth and death. Direct violence and physical strains to which the poor are subjected in lifting the proverbial coal bucket and in active exercise in domestic work, especially over the wash tub. Manufacture work by pregnant women in badly ventilated buildings, amid poisonous fumes and with machinery which constantly racks and jars the operator is a frequent cause of miscarriage and premature birth. Time will not permit the consideration in detail of the many maternal and fetal causes of this slaughter which could be diminished greatly by intelligence and skill.

The question of feeding the newborn and infant is paramount in a discussion of this subject. More cases of atrepsia, malnutrition, and acute gastro intestinal disturbances with a fatal ending have their origin in an improper diet during the first few weeks of life, than from any other cause. I do not believe there are as many mothers who wilfully discontinue nursing too early or refuse to put their babies to the breast, as some would lead us to think. It is difficult to believe that any mother who is capable of doing so would refuse to nurse her infant after the dangers of artificial feeding have been carefully explained to her.

There are cases which do not seem to thrive upon the breast, or where from the slow appearance of the milk the infant loses so much ground, that even after the milk comes a normal gain is very slow, or the child so reduced as to be greatly jeopardized. Owing to the infrequency with which the infant's temperature is taken, during the first few days, or more than a casual glance given it by the attending physician, starvation temperature is not recognized and valuable time is lost by the policy of doing nothing or waiting developments. The judicious administration of several feedings of a properly modified milk at this time will save much suffering and start the baby off properly when nature supplies the proper amount of breast milk. I would not be misunderstood as advocating the artificial feeding of all infants during the first week. It is the exception that this is indicated, but the intelligent recognition of the cases in which it is needed will save many babies.

In spite of opinions to the contrary, I am convinced that the proper interpretation of the infant's weight curve will do much toward saving babies and preventing their becoming so attenuated and reduced as to easily be a victim of any intercurrent infection or gastro-intestinal disturbance. I have had under observation during the past few years,

several such cases. These babies were bright, happy and contented, bowels for the most part normal and regular. Because of these facts they were not weighed for a number of weeks, only to find when weighed, that they had not gained. It was with difficulty in all of these cases, that the proper adaptation of their food could be made to meet the demand of nutrition and cause a proper gain in weight. Any illness in a child of this kind is very poorly borne, this being especially true of the acute exanthemata, pertussis, pneumonia and the gastro-intestinal disorders. I do not plead for the universal adoption of the finer mathematical formulæ in milk modification or adaptation, but do advocate a more serious and careful study of the subject by the general practitioner. By learning to think in percentages of milk and milk mixtures far better results will be obtained in those unfortunate infants deprived of a nourishing breast milk early in life, and must of necessity be put upon an artificial food. Just here I wish to go on record as advocating an adapted or modified cow's milk for artificial feeding to the entire exclusion of all artificial or prepared foods on the market. Some of these may have some place in the very temporary feeding of infants, but they are all found wanting as a continuous food, and are the cause of many nutritional disorders leading finally to serious morbidity or even a fatality.

It is a sad commentary upon the medical profession that so many of the newer organizations looking to social uplift of the people are controlled to a great extent by the laity and have but few physicians actively interested, their policies being dictated almost entirely by the laity. Physicians should recognize the intimate relation between social conditions and diseases, and the fact that this is more true of infants and children than with adults.

The community plan of caring for infant welfare is productive of the greatest good in the reduction of infant mortality. Wilbur Phillips has estimated the average cost of caring by preventive methods for the health of one baby for one year is \$6.00, and the average cost to parents in Milwaukee to rear babies to the average age to which they die (about four months) of paying for confinement, for baby carriages, doctor's bills, etc., is \$120.00. He estimated then that saving the death of one baby would pay the community for providing medical and nursing supervision for twenty babies for an entire year. By establishing stations in the localities where statistics show the greatest morbidity and mortality to be, which would be a center for dispensing clean cold milk, for caring for the mothers of all babies in the district, provid-

*Jahrb. f. Kinderheilkunde, 1902, xxxv., p. 9.

ing medical and nursing service, to be paid for by the city, many babies will be saved to society and a great financial saving brought about to the community.

This has been proven in Louisville through the efficient work of the Babies' Milk Fund Association, it having been estimated by the City Health Department that the infant mortality during the past year has been reduced fully fifty per cent. through this agency alone.

This has been accomplished by carrying the gospel of clean milk into the homes by efficient trained nurses, by teaching these mothers how to care for the milk in the home, the scientific care of the child, feeding, bathing, clothing and daily routine of life. They teach the mother how to recognize when the child is sick and the necessity of reporting such condition at once rather than allow "nature to take its course." If no such organization exists in your city, and yours, interest the club women and philanthropists, and start one at once, keep in touch with the work and direct their activities and become instrumental in stemming the tide of the wanton destruction of the innocents through ignorance of right living.

ENDOMETRITIS.*

By WM. L. MOSBY, Bardwell.

Endometritis is an inflammation within the uterus involving the mucosa but may terminate in the deeper structures by contiguity. It usually extends from the cervical canal upwards but may descend from the ovaries and tubes to the uterine cavity secondarily.

In the etiology of endometritis we may find any of the pathogenic bacteria ordinarily found in the genitalia either individually or in mixed form responsible for the local infection including the staphylococci, streptococci of suppuration, bacillus of tuberculosis, bacillus coli communis and the pneumococcus of Frankel.

Bladder parasites and the saprophytes from the rectum and colon are conveniently accessible to the genitalia for its infection.

The bacillus coli communis lives in an acid media so it will easily pass through the acid vaginal secretions to the uterus to excite inflammation.

The gonococcus of Neisser, a destructive and frequent factor in etiology of endometritis is responsible for many of the severe infections met with in practice. It may remain quiescent in the mucous crypts for the longest period and then spread to the endometrium with all the virulence of a real active inflammation of this anatomic structure.

The predisposing causes of endometritis are any condition favoring pelvic congestion especially when associated with anemia, tuberculosis or any debilitating constitutional condition; menstruation, suppression of menses, uterine displacements, abortion and parturition, traumatism, excessive coitus, etc.

The micro-organism discussed under etiology of endometritis are present as an essential factor in the production of this pathologic condition when added to the predisposing local and constitutional defects mentioned. Normally the cervix and corpus uteri are free from pathogenic bacteria but when invaded they will be active or inactive according to the resisting powers excited by their presence.

The uterine mucosa is penetrated with a great number of tubular glands well adapted to the incubation and distribution of infective bacteria so that the tendency of these inflammations is to become chronic and resist treatment. It is lamentable that so frequently have the surgeon's fingers or his dirty instruments carried infection to a healthy uterus, in parturient and other instrumental cases, indeed the intra-uterine use, or *mis-use*, of the sound without proper sterilization and sufficient justification for its use should be condemned as dangerous practice. Unnecessary explorations and local treatment have carried the infection from a harmless field to one of more danger with increased virulence and in more than one instance have I seen abortions produced by this formerly frequent and vicious form of so-called treatment. Histologically we have the glandular form of endometritis which may be either hypertrophic or hyperplastic and the interstitial, which may be glandular and interstitial combined. In the glandular variety there is augmentation of glands both as to size and number. Hypertrophic endometritis causes increase in size of glands and variation of the perpendicular arrangement of canal, they become more tortuous, extends deeper in or through the mucosa, become constricted in some portions and dilated in others. These glands are lined with columnar epithelium and under the stimulus of disease each individual cell undergoes enlargement.

The hyperplastic form may be characterized by all the essential features of hypertrophy but with increase of number of glands actually present. This increase means a corresponding decrease in the interglandular tissues so that the ratio of four to one may be changed or even inverted. This increase is produced by constriction and invagination of the gland by inflammatory action.

In the interstitial form of endometritis the hypertrophy or hyperplasia applies to the connective tissues and this augmentation de-

*Read before the Kentucky State Medical Association, Louisville, October 30, 1912.

stroys the normal utricular glands, increasing the normal connective tissue.

In the destructive process of inflammation the glands may degenerate into retention cysts by closure of outlets. The mixed form includes the mucus polypi and occurs where interstitial inflammation is associated with the glandular enlargement.

The presence of these growths will usually be accompanied by profuse secretion and hemorrhage is more common than in other varieties of endometritis.

Clinically we may recognize a number of forms of endometritis arising from different etiologic factors and varied symptomatology in each individual case according to the fancy of the gynecologist but practically they can usually be referred to some of the histologic arrangements assigned above.

Want of time will prevent a consideration of the clinical varieties suggested by leading features of the case such as septic, gonorrheal, senile, tubercular, traumatic, etc., as these clinical data are useful only as suggestive to therapeutic management of patient and should only be so considered. Endometritis following labor, abortions, intra-uterine trauma, gonorrhea and septic infections will be acute and subject patient to grave danger unless severity of attack is modified by prompt therapeutic measures.

In the acute form the on-set is sudden and ushered in by a distinct chill, followed by fever of moderate degree, with quick pulse. may be nausea and vomiting and also diarrhea sometimes occurs, attended with rectal and vesical tenesmus. Pains more or less severe in the pelvis and loins are usually present. Rigors, recurring at frequent intervals with temperature, either intermittent or remittent, is present. After a few hours a mucus discharge appears which later becomes purulent and is sometimes mixed with blood. Salpingitis and even peritonitis may follow these virulent infections with all the formidable symptoms and dangers that attend these grave conditions or the acuity may gradually pass away and the symptoms become sub-acute or chronic with a milder form of local and systemic symptoms.

The chronic form of endometritis is so insidious usually that the patient cannot always recall the first appearance of the disease unless it follows the acute form.

Leucorrhea is more profuse where the glandular structures are extensively involved and correspondingly less atrophic changes have occurred. Where mucus polypi or fungoid development exists the discharge is more purulent.

Hemorrhage when present is due to hypertrophy of the mucosa and may be profuse either as a menorrhagia or as a metorrhagia

where fungoid or polypoid changes occur in the endometrium but in other conditions menstruation may not be disturbed.

Pain is not infrequently present but has no special pathologic or clinical significance, but is rather to be attributed to associated or underlying pathologic conditions, however, the sensitive nerves of the inflamed mucosa will produce pain in some individuals or a localized character, while in others it may be entirely reflex and referred to the vertex or occiput or even lower spinal region or to the hypogastrum. Patients are often neurasthenic or nervous, sometimes to the extent of hysteria, and great mental depression with disinclination to mental or physical exertion with unusual inclination to fatigue may be present. Alimentary disturbances, marked by disposition to flatulence and constipation, are frequently present and contribute no little to discomfort of patient and aggravation of the pelvic congestion. The diagnosis can only be made by the history of the case, local and general symptoms combined, aided by the sense of touch and sight and the use of the microscope. Touch reveals the presence of laceration of the cervix, displaced uterus, patulous os, subinvolution or any alteration in size or shape of organ with unusual tenderness to touch and if deviation from the normal as to softness or hardness exists this is also noted.

Sight, aided by the speculum in situ, reveals the presence of a discharge from the os uteri and its character but when a microscopic examination is necessary, where we suspect gonorrhea or sepsis and wish to differentiate the pathogenic bacteria present, we should first remove the mucus from the cervix carefully before obtaining the discharge from the corporeal utricular glands.

Where curettment is necessary and malignancy is suspected, we should avail ourselves of the services of the pathologist to examine the scrapings for possible degenerative changes.

TREATMENT.

In the application of remedies in the treatment of endometritis we should consider the severity of the infection, whether confined to the cervix or the body of the uterus, whether recent or chronic and what bacteria are responsible for the inflammation present, if possible. Constitutional defects should be corrected in so far as is possible and etiologic factors both predisposing and exciting should be removed.

Where there are local causes for infection it should be carefully and completely removed by indicated medical or surgical measures with as little meddling as possible. Where placental tissues are retained they should be removed and the uterine cavity irrigated with

bichloride solution 1-2000 followed by normal salt solution twice in the twenty-four hours until symptoms show signs of improvement without which we may curet after forty eight hours if favorably situated and possessing sufficient skill and the environments will permit.

Where gonorrheal infection is responsible for the endometritis and the attack acute and severe we should at once dilate and curet and follow by intra-uterine irrigation with sublimate solution. Pure carbolic acid may now be applied to the endometrium to destroy remaining bacteria and prevent reinfection. Absolute rest in bed for one week should be enjoined.

Where constitutional dyscrasia are present as a etiologic element in the case we will require little or no local treatment but improvement of the general health by the administration of indicated tonics, improved hygiene, proper food and exercise, regulation of bowels and kidneys and removal of local conditions favoring congestion and sources of infection if any. Briefly we would say treatment is constitutional, local and surgical, according to indications.

In the systemic application of remedies the therapeutic fancy of the gynecologist with pathologic indications will determine the measures to be adopted in safeguarding these cases as the drugs used are too numerous to mention and must be determined by conditions present in each individual case.

The topical application of medicaments to the endometrium as a "routine" can not be too severely condemned and the pernicious habit of intra-uterine exploration with the sound without proper preparation of the patient and the complete sterilization of all instruments and even then without adequate indications for so doing, is attended by great danger and is not practiced by the best gynecologic surgeons of to-day. Avoid intra-uterine medication except there is positive indication and then only under strict aseptic or surgical environment.

Strong applications of both antiseptics and caustics are more potent for evil than for good and their frequent and improper use may destroy the endometrium and injure the deeper structures of the myometrium, producing new pathologic conditions that may require surgical measures to relieve.

The remedies used for local treatment are more numerous than efficient, so we shall only mention those most frequently relied upon and we might say the more dependable measures for this purpose; creolin, iodine, carbolic acid, ichthyol, iodoform and formalin as the best therapeutic agents.

We deem it unnecessary in this connection to elaborate the methods of topical treatment

but would emphasize the importance of securing thorough dilatation before these applications are made otherwise mischief may be done.

Curetage of the uterus should be done in the infectious and chronic forms of endometritis that have proven rebellious to local and constitutional methods of treatment.

The technique of this valuable expedient we shall not discuss before you but pass by suggesting the same thorough care in preparation of patient and aseptic surroundings as for any abdominal operation.

Where inflammation exists in the adnexa with immovable uterus, sensitive to the touch, there is increased danger of lymphangitis or peritonitis. Formerly salpingitis, ovaritis and peritonitis were considered contraindications for uterine invasion for treatment but now they only suggest greater care in operative procedure and demand the complete removal of all diseases mucosa.

The dull curet, like the uterine sound, in these cases are to be equally condemned as they open up new avenues and supply fresh material for infection and are powerless for good.

This important gynecologic operation should be done only under proper surgical environments and with sufficient surgical skill to promise patient all that modern gynecology offers these unfortunate sufferers.

VASCULAR TENSION IN CHRONIC ILLNESS.*

By J. D. MUTTERS, Ashland.

The normal metabolism of the human body requires the supply of food quantitatively and qualitatively of the proper kind, the laying up of this food within the body, a regular chemical transformation of the tissues, and the formation of the effete products which have to be given out through the excretory organs.

In order that normal metabolism may go on there must be quiet, even flow of the blood-stream in the vast capillary areas, everywhere flooding the tissues with nutriment and oxygen. The flow of the blood-stream from the heart into the arteries is an intermittent flow. The conversion of this intermittent flow into a quiet, even one, (as observed in the capillaries), is due to the elasticity of the arteries, and the peripheral resistance. This brings us to the consideration of blood-pressure.

The factors which determine the blood pressure at a given moment in any individual, are the power of the heart, the volume of the circulating blood, the elasticity of the arteries, and the resistance to the flow.

*Read before the Kentucky State Medical Association, Louisville, October 29-31, 1912.

The blood-pressure depends in the first place, upon the strength of the ventricular contractions, and, since the work of the heart depends upon the volume of blood discharged into the aorta, the velocity imparted to it, and the aortic pressure overcome, it is plain that a difference in blood-pressure may be brought about by a change in either the power of ventricular contraction, or the volume output of blood. Any increase of the power of the heart, in the volume output of the ventricles causes a rise in pressure, and any diminution a fall if the peripheral resistance remains unchanged.

The total blood-volume is small when compared to the full capacity of the arteries, capillaries, and veins combined. This disproportion is compensated for, in the normal individual, by the continuous contraction of the smaller arteries; in other words, by the vaso-motor tone. Therefore, the volume of circulating blood, (within certain wide limits), has in the normal individual, only a subordinate and temporary influence on mean blood-pressure.

The elasticity of the arterial wall is a mechanical device of great importance. In it during the contraction of the heart a large part of the power of the ventricles is made potential, to be utilized in moving the blood during diastole, thus converting an intermittent into a continuous propelling force, and distributing the hearts work over more than twice the time of its actual muscular contraction.

The elasticity of the normal arteries is very perfect, they may be much distended by pressure and subsequently resume their original size. It is this property of elastic distensibility which is so important. It is safe to assume that a healthy artery cannot be torn by any increase in blood-pressure which is possible during life.

The limits of elasticity of the arteries vary with the internal tension to which they are subjected. Experiments have shown the greatest elasticity at about the lower limit of normal blood-pressure for the animal, the elasticity decreasing at higher and lower pressures. Other experiments have found the maximum in the unstretched artery, and progressive loss of elasticity the higher the absolute pressure was raised. From the observation of investigators, at least one fact seems secure; viz.: at a high arterial pressure the distensibility of the arteries is distinctly diminished, and any increase in the systolic pulse-volume must raise the blood-pressure far more than a corresponding increase at lower pressures.

Since normally there exists a considerable pressure within the arteries, there must be a well-marked resistance as its cause. Between

the arteries and the capillaries are the arterioles. The main resistance to the passage of blood through the tissues is situated in the arterioles, and not, as formerly taught, in the capillaries. The really effective cause, however, is the so-called tonus of the blood-vessels. From the standpoint of the blood-pressure and its variations, the vasomotor mechanisms are by far the most important facts in circulatory physiology and should be studied carefully by all who attempt the interpretation and clinical use of blood-pressure determination.

The vaso-motor-tone is an absolute necessity for the maintenance of the circulation. The tonus of the blood-vessels varies constantly in particular areas, in response to local needs. This is a physiological necessity, since increased function of a part must always be accompanied by increased blood-flow.

Of all the parts of the vascular system, the abdominal vessels, enervated by the splanchnic nerves, have by far the greatest effect on general blood-pressure. This is one of the most essential facts to bear in mind clinically. If the blood-pressure rises to a point where the heart is embarrassed, reflex dilatation of the countless arterioles of the abdominal viscera, evoked by the depressor nerve, promptly causes a fall. Therefore, an abnormally high blood-pressure cannot exist permanently, unless there has been some damage to the regulating power of the visceral circulation.

With increase in peripheral resistance, increased cardiac energy is required to keep the same volume of blood flowing through the capillaries, and, if it is lasting, the working ability of the heart must be raised to a higher average level, and this necessitates more or larger muscle fibres. Hence, permanent high blood-pressure cannot be maintained without hypertrophy of the heart. We find the most complete confirmation of these conclusions in the case arterio-sclerosis when the splanchnic arteries or the aorta above the diaphragm are highly disensed.

Permanent high blood-pressure is one salient feature of chronic interstitial nephritis. From the standpoint of diagnosis, hypertension is of great importance in connection with the contracted kidney. It is one of the most constant and, with the sphygmomanometer, most easily detected evidences of the disease. Patients with chronic nephritis frequently consult a physician for nervous symptoms, precordial distress, on exertion, some shortness of breath; auscultation of the heart is negative, and because of obesity enlargement of the heart cannot be made, a single examination of urine may reveal anything suggestive of renal disease. The great advantage of blood-pressure measurements is, that hyper-

tension will certainly be detected, and this will put the physician on the alert.

From the standpoint of prognosis, a gradually increasing pressure which resists treatment, is of bad significance when there are any symptoms of cardiac insufficiency, because increasing the work of the already overtaxed left ventricle.

Another feature in prognosis is the danger of cerebral hemorrhage. It has been well established that this is a common termination of Bright's disease.

Again the sudden development of a rising blood-pressure, may indicate the onset of uraemic manifestations, and deserves immediate attention. There seems little question that the uraemic manifestations, that is, headache, vomiting, and disturbance of consciousness, run closely parallel with the blood-pressure.

In the investigation of arterial disease, only a small portion of the great arterial tree lies within reach of ordinary methods of physical examination, the most important branches, those to the abdominal viscera, are entirely removed from approach. The sphygmomanometer is therefore a useful adjunct to other measures of examination.

There is a class of cases that show high blood-pressure, but neither discoverable arterial thickening, nor any clinical evidence of nephritis. These cases are important ones practically, they must be considered as having a permanent augmentation of peripheral resistance in the arterioles, especially in the splanchnic circulation. This condition has been termed "angino-sclerosis," the recognition of which is much easier by the sphygmomanometer than by the ordinary methods of examination.

In the diagnosis of angina-pectoris well marked hypertention is important evidence, especially in the case in which no anatomical changes can be found by ordinary physical methods of examination.

Permanent high-blood-pressure is a source of altered function throughout the circulatory system, which leads to further secondary changes, as for instance, structural alterations in the heart muscle, and sooner or later the power of such a heart will become insufficient for the demands upon it.

The elasticity of the arterial wall decreases under the influence of permanent high blood-pressure and dilatation of the arteries may take place.

Finally permanent high blood-pressure should be looked upon as an evidence of a toxemia and as a symptom complex in a great variety of conditions.

COMMON DISEASES OF THE EYE IN CHILDREN FROM THE STAND- .. POINT OF THE GENERAL PRACTITIONER.*

By GAYLORD C. HALL, Louisville.

It is not the hope of the writer to bring forth anything new or startling, either in the conception or treatment of the diseases under consideration but rather to emphasize and bring to the attention of the general practitioner a few well known and homely facts regarding the examination, diagnosis, and treatment of the commoner diseases of the eye as seen in childhood.

I first wish to call your attention to the matter of examination for I think that most of the failures in the treatment of these conditions start here.

Three of the most prominent symptoms in external diseases of the eye consist in pain, swelling, and sensitiveness to light, all three of which are factors contributing to a difficulty of an examination and it is perfectly evident that one who goes about an examination half-heartedly will learn very little about the real condition of the patient's eyes.

One should proceed deliberately and thoroughly, using as little force as is consistent with the thorough inspection of the parts under examination.

The most satisfactory method of making an examination in young children is to provide two chairs with the apparatus for examination on a table conveniently at hand. This apparatus should consist usually of a suitable lid retractor, a light of some kind, and a condensing lens.

In one chair let the mother or nurse sit holding the child in her lap, the examiner sits in the other chair holding the head of the child firmly between or on his knees so as to take advantage of a good light.

Spasm of the lids will of course result as soon as an attempt of examination is made but a little persistence on the part of the examiner will soon result in the overcoming of this and usually an examination of the external eye and particularly the cornea is possible as the spasm relaxes.

If this spasm can not be overcome by using the fingers a lid retractor will of course have to be called into service and should be used as gently as possible, pulling the upper lid not only up but away from the eye-ball, when the parts can be thoroughly inspected.

I have gone somewhat into detail regarding the method of examination since nothing will so inspire confidence in the patient as seeing a man go about an examination in a thorough-

*Read before the Kentucky State Medical Association, Louisville, October 30, 1912.

ly competent and business-like manner. What is more important, however, it enables the physician himself to ascertain the structure at fault and thus he is thoroughly armed in the management of the case, since he has the confidence of the people and a knowledge of the diseased condition.

Supplementing this it is well to instruct the people in charge of the case as the examination is being made that this is always the most satisfactory position in which to instill medicine in the eyes, for it is futile to examine and diagnose if the medicine which will cure the case is not thoroughly and conscientiously used.

I wish to dwell in particular upon these points since I feel confident that it is this indifference or diffidence on the part of the general practitioner which often results in failure, where the same line of treatment with these factors eliminated would have resulted in success.

Let us consider briefly some of the diseases common in childhood.

CONJUNCTIVITIS.

Old classifications of this disease are catarrhal, muco-purulent and purulent. This should be eliminated since it conveys no information regarding the source or type of infection. It is far better to classify these types of inflammation according to the infective agent present and it has a further important bearing regarding treatment.

The acute epidemic conjunctivitis popularly known as pink eye may be caused by one of several organisms, the Koch-Weeks bacillus and the pneumococcus being the most common cause. There may be associated a staphylococcus or streptococcus infection or the infection may be continued by the presence of the xerose bacillus.

These infections yield usually to weak silver nitrate solution from one-half to two per cent. used by the surgeon with the instillation by the patient of some of the newer silver preparations four or five times a day, such as argyrol in twenty to fifty per cent. solution.

Another infection of the conjunctiva that is of especial importance is the bacillary conjunctivitis or otherwise called Morax Axenfeld conjunctivitis.

In contradistinction to the epidemic conjunctivitis, which is a disease prevalent in cities and crowded districts, Morax Axenfeld conjunctivitis occurs often in rural communities, is not especially inclined to become epidemic and is a disease of many and various manifestations.

It sometimes occurs at one corner of the eye, the so-called angular conjunctivitis, there being simply a slight redness of a circumscribed area and a white scum along the lid mar-

gins, which may show some degree of blepharitis.

In other cases the entire conjunctiva may be involved with considerable purulent discharge. In severe cases the cornea itself may be infected and the case go on to considerable destruction of tissue. These types are, of course, uncommon. Examination of the secretion taken preferably from the internal canthus show the diplo-bacillus which is the cause of the infection.

It is here that bacteriology comes into prominence as a diagnostic agent for the silver salts which were effective against the Koch-Weeks bacillus, pneumococcus, staphylococcus or gonococcus are singularly ineffective in this condition.

Salts of zinc are probably specific and a solution of from two to four grains of sulphate of zinc to the ounce of water will speedily clear up any ordinary case of this trouble.

OPHTHALMIA NEONATORUM.

The ophthalmia of the new born, practically the gravest and most dreaded of all diseases of childhood comes as a heritage to the infant within a few hours after its birth.

While in a vast majority of instances the gonococcus is the infecting agent it is to be remembered that other bacteria may be responsible for as severe an ophthalmia as the first mentioned organism.

It is useless to say that the most prompt and energetic measures should be instituted the moment even a suspicion of the trouble exists and I recommend the prophylactic instillation of nitrate of silver immediately after birth in the eyes of all children, regardless of their record, wealth, or social condition of the parents or of a negative history.

In these cases it is of the utmost importance to obtain an accurate view of the eye at the beginning, repeating the examination as often as is necessary to retain a clear conception of the progress the case is making.

It is to be remembered that immediately after birth swelling of the eyes may be due to edema, to pressure from instruments, or the instillation of nitrate of silver, and while suspicious, is not alarming.

At the onset of the case all those who come in contact with it should be informed of the infectious nature of the trouble and warned in the proper care of their persons. They should also be instructed regarding the disposal of all things which come in contact with the infected eyes.

If one eye is clear it should be suitably protected. A celluloid vaccination shield with the air holes covered makes a suitable protecting agent.

The infected eye should be first carefully cleansed with warm saline or boric acid solu-

tion, saline preferred, taking care that the accumulated secretion in the culdesac is thoroughly evacuated; following this, installation of one to two per cent. nitrate of silver should be made with the lids everted and immediately following this a solution, from 25 to 50 per cent. of argyrol should be instilled. Allow the lids to resume their normal position and in a minute or so, upon again everting them, a brown film or pellicle will be seen over the surface. This should be gently removed by mopping and argyrol again instilled repeating this several times until the pellicle no longer reforms.

This is extremely important since most of the discomfort arises from strings of secretion irritating the eyes after the instillation of the medicine; unless this be carefully removed the patient fears the treatment almost more than the disease whereas if removal is carefully done he has a grateful sense of relief following the treatment.

This part of the treatment should be done by the physician himself; following his visit the nurse in charge should be instructed to keep the eyes clean by washing with the salt or boric acid solution every half hour if necessary, every two hours instilling the argyrol solution after washing.

Ice cloths are often very grateful early in the disease but should be used with caution in the very young as apt to disturb the nutrition of the cornea. Hot applications also have their place later on or the two may be used alternately.

Complications consist chiefly of great swelling of the lids which if not controlled by cold applications is best relieved by local blood letting. For this purpose take a pair of blunt pointed scissors and cut outward from the external canthus as far as the external wall of the orbit.

Marked chemosis of swelling of the ocular conjunctiva literally submerging the cornea and interfering with its nutrition may have to be relieved by snips of the scissors in the swollen conjunctiva placed radially around the cornea.

The most feared of all complications in this disease is ulcer of the cornea. The best treatment is preventive, by early energetic measures in every case and especial care in seeing that no treatment results in the slightest injury to the protective epithelial covering.

If it occurs in spite of these precautions, hot applications, atropin, to keep the pupil dilated—with redoubled care and energy in the local treatment; if the ulcer shows a tendency to spread, curettment or better cauterization with pure phenol followed by alcohol and an oil dressing is in order.

In spite of our best efforts some cases go on to extensive ulceration of the cornea and even

perforation with subsequent loss of vision.

But one case of this kind were needed, it would seem, to rouse the community to a determined effort to stamp out such a foul disease. Yet we find that these cases still constitute the bulk of the blind in our institutions.

PHLYCTENULAR DISEASES.

One of the most common as well as the most important of the diseases of childhood is phlyctenular conjunctivitis or keratitis. The most important symptom of this trouble is photophobia, which is intense. The discharge from the eye is usually of a watery nature and differs from that of the regular conjunctivitis.

The attack is characterized by the eruption over the cornea of little blebs filled with clear liquid at first, which becomes purulent before rupturing, at which time the ulcer presents a smooth punched out appearance usually with vessels running to it from the sclero-corneal margin, particularly if it has proceeded for any length of time.

These cases, by the way, are exceedingly difficult to examine, but the characteristic expression of the child who holds his eyes almost shut; and he will invariably shut them when you tell him to open them; together with the extreme photophobia should put one on their guard for the diagnosis of this condition.

Probably nothing better illustrates the futility of treating the local condition alone in the hope of a cure than in a case of this condition. These children are at fault constitutionally, often suffering with profound intestinal intoxication. There is usually a history obtained of over indulgence in sweets with a consequent deficient assimilation of other foods.

The bowels are often constipated and considerable intestinal putrefaction is evident. Often the hair is dry and brittle; the skin pasty and white with a deposit of a considerable degree of adipose tissue.

The case may be also complicated with extensive eruptions on skin of the lids or face, hair, or on other parts of the body.

It is also known that these cases are recurrent since following the attack the patient is very apt to resume the habits which actuated the first attack and it is well to bear this in mind and notify the parents to prevent a relapse into the old habits.

There has been a recent attempt to establish a relationship between this trouble and tuberculosis. Certain it is that a number of these cases give tubercular skin reaction and it is well known that the instillation of tuberculin in the conjunctival sac in a case thus afflicted resulted in a violent reaction. Up to the present, however, there has been no absolute proof that a cause of relationship exists between this disease and tuberculosis.

In the matter of treatment one of the first things is to give a thorough purgation, this to be followed by a general tonic.

Syrup of lactophosphate of calcium alone or combined with iron or the hypophosphate compound in suitable doses is recommended.

The diet and habits of the child should be rigidly inquired into and all sweets forbidden.

Finally, to the eye itself yellow oxide of mercury in one grain to the drachm applied three times a day is in some cases a specific; in others it fails to give the desired results.

If the ulcers show a tendency to enlarge or coalesce it has been my habit to touch the edges with pure carbolic acid which often brings about a very rapid healing. This of course should be done under local anesthesia and under perfect control followed by an immediate application of ointment. I have often found a combination of resorcin and salicylic acid with the mercurial salts would bring results where the yellow oxide alone failed. It must be remembered, however, that no amount of purely local treatment will cure the tendency to recurrence of this class of cases and an intelligent co-operation between the doctor and patient is absolutely essential for success.

BLEPHARITIS.

Blepharitis or inflammation of the lid margins occurs in two forms. One a dry variety with accumulation of dry scales around the base of the lashes; and a small zone of inflammation on either side. It is often exceedingly rebellious to treatment by local measures alone and should direct one's attention to a possible refractive error. Recurrent hordeolum or chalazion should awaken a like suspicion.

The other form of blepharitis is more severe with abscess formation around the lashes, which are covered with heavy crusts and on removal show shallow ulcers with a yellowish base. The edges of the lids are usually thickened with corresponding inflammation of the conjunctiva; other portions of the body may also be the site of the disease.

In the treatment of these conditions locally the first requisite is to remove the scales or crusts. This can be done easily by gently mopping with a solution of peroxide of hydrogen made alkaline with bicarbonate of soda at the time of using. After removal of these we are ready to treat the underlying disease.

Ichthyol does well in some cases. Probably the most widely used remedy is the yellow oxide of mercury ointment, a grain to a drachm. This should be carefully examined to see that the yellow oxide is thoroughly incorporated for the fine granules not rubbed up, which may be seen in the ointment look like little grains of red pepper and burn like them also.

I often incorporate a small quantity of resorcin and salicylic acid in this ointment

which seems to aid its action greatly in some cases.

As in phlyctenular troubles it is essential to inquire into the general health and in particular to correct the diet, building up the general health by appropriate tonics, not forgetting that these symptoms of external inflammation may be only the plea of the eye for relief from a refractive error.

TRACHOMA.

Trachoma is a social disease and demands mention here because every child on entering school life may be exposed to infection.

A study of the pathology of the disease gives us the indications for treatment. It is first a productive inflammation with hypertrophy of the lymphatic tissue in the lids manifested by the presence of granulations. After a varying period of time atrophy takes place which involves the whole palpebral conjunctiva.

It is this atrophy that is directly responsible for most of the baneful effects of the disease, by binding down the lids it produces pannus and indirectly the scarring of the cornea; also the trichiasis and entropion and ptosis so characteristic of this trouble.

The problems presented in this case are, first, the eradication of the granulations; second, the prevention of the effects of the atrophy or the relief of the atrophy after occurrence.

The first is best accomplished by some form of expression or removal surgically. The second by division of the canthal ligaments and excision of a portion of the tarsal plate.

It will be seen that the treatment of the disease is almost purely surgical. I have drawn attention to this disease for two reasons. First, to show the futility of attempting the condition with drops, washes, or by painting with blue stone.

Secondly, to call attention to its social characteristics, its infectionness and the desirability of its prevention.

There is but one solution of this difficulty, namely, education and the efforts already made along this line by some of the doctors in Lexington in their work in the mountains deserve the greatest praise.

Every doctor in the State should do all in his power to aid in the eradication of this disease.

STRABISMUS.

This paper would not be complete without a brief reference to strabismus. This is a condition of all others first seen by the general practitioner and most often neglected.

I wish to impress most strongly upon the memory of every one here that in these conditions one can not begin to treat the case too soon. As one writer has put it, a child old enough to squint is old enough to wear

glasses. While that may not be true in every case, at least we can say that a child old enough to squint is old enough to receive treatment for it.

The things to be borne in mind are that treatment should be carried out from the earliest inception of the disease because deferring treatment either takes a defective eye and makes it blind or takes an otherwise good eye and makes it defective.

Second, the child will not outgrow the condition but will get progressively worse.

Third, above all things, that an operation will not restore the visual acuity; that operative measures are simply a court of last resort to render the visual axis parallel and have nothing to do with restoring a person's power to see.

It is understood, of course, that I am speaking here of the ordinary concomitant convergent strabismus. I am not referring to paralytic conditions.

The treatment that the writer has found most effective is the following: First, a solution of atropin, usually one-half per cent, is used for a week or ten days three times a day in both eyes. This procedure in itself will often render the eye straight since it prevents the overbalance due to near work.

Following the use of atropin the child should be carefully refracted. If too young to refract from the trial case and test type, and they should be, these cases should be refracted by the retinoscope and a full correction given.

I have had a number of these cases to refract under these conditions and have been gratified to find that when the child grew to the age where it could answer questions from the test type there was little or no change to be made in the retinoscopic findings.

If the child is old enough attempts should be made at the start to determine how much loss of vision there exists in the eye which turns in. If none can be discovered the case is much more simple. If, however, serious impairment of vision is discovered in the squinting eye it will require months of steady hard work to restore this eye to anything like normal vision.

Following the atropin in both eyes one should discontinue the atropin in the bad eye allowing it to return to its normal state. This will allow the bad eye to be used for all near work and will train it in excess of the good eye. This should be further supplemented by covering the good eye for an hour or two every morning and evening forcing the child to do all things with the defective eye.

A word about the instrument of Worth. Claude Worth, of London, believes the essential cause of strabismus to be a lack of development of the fusion faculty, a center in the

brain which takes the images from the two retinas and fuses them into one. This center normally should be fully developed at the age of seven years, therefore if we expect to establish binocular single vision it is necessary that the child be trained before the end of the period of the development of the fusion faculty.

For this training his instrument, which has been modified by Dr. Black, is extremely useful in stimulating binocular vision in these cases. I have used this instrument for the past four or five years and can testify to its value.

In addition to this office work, home training by the parents or by the teacher at school is the work which does probably the greatest amount of good and the parents should be instructed in the conduct of the case.

So firmly ground has become the belief that an operation is all that is necessary for the handling of these cases that actually it is hard to convince parents at times that the method of treatment that I have laid down is the proper one to pursue. They often feel like they would rather take an operation and have it over with as being easier for all concerned but they fail to appreciate the real crux of the situation in that while an operation will restore the parallelism of the axis it will not restore the sight in the defective eye.

It should not be forgotten that the various infective fevers of childhood threaten not only the external optical apparatus but sometimes the fundus of the eye ball. Cases of iritis, cyclitis, choroiditis, and optic atrophy have been reported as a result of such diseases.

Cases of this description, however, belong more especially to the specialist in eye diseases and are simply mentioned here in passing.

Among the diseases mentioned in this paper there stand out two notably ophthalmia neonatorum and trachoma that are absolutely preventable and if every one did his duty would be completely stamped out after a time.

It is the duty, therefore, of every doctor in Kentucky to be alive to the best interests of his patients and educate them as to the cause and prevention of these two diseases.

He should further be interested in any legislation looking to the regulation of the practice of and licensing of midwives to control ophthalmia neonatorum.

The vast bulk of the trachoma in Kentucky exists in the mountains where a campaign of education is already started.

Other sections of the State, especially where foreign labor is being imported, should be alert to detect its presence so that they can stamp it out in its incipency and not have a trachoma problem on their hands.

ENTERIC THERAPEUSIS IN CHILDREN.*

By P. F. BARBOUR, Louisville.

Enteric therapeusis is a term which embraces so many things it is impossible in the limits of time to discuss more than the therapeusis of the diarrhoeal disorders. Before one can formulate a therapy, one must have a clear cut conception of the condition for which treatment is demanded. Unless one understands the conditions which are present in the intestine, he is hardly capable of adapting his remedies intelligently to attain the results at which he is aiming. There are many types of diarrhoea in the adult, which are found so rarely in children, as to be practically negligible. The diarrhoeas of uremia, tuberculosis and certain eliminative disorders, are exceedingly rare in childhood. For practical purposes one must class the diarrhoea of children under the following heads: It is either irritative or infective in its origin.

Irritative forms of diarrhoea include those which are due to the use of food that is wholly unsuited to the child. The infective diarrhoeas are, as their name implies, largely due to special forms of infection by micro-organisms. These two terms, however, are used in a very general sense and will require considerable elucidation, in order to express the ideas for which the words have been selected. Irritative diarrhoea results from the use of food which is not suited to the child at that particular time. This includes not only the well recognized substances, such as cucumbers, cabbage, fried meats and over-ripe fruits, but also many foods which are not in themselves unsuitable, but which the child at that particular time, through its constitutional tendency, is unprepared properly to handle. It is a well known fact that children are not able equally at all times to digest the same foods. The list of unsuitable foods can be added to by any one with experience in the treatment of children. One will often notice that there are inherited capacities or incapacities to digest certain general types of food products; again one will often observe in young children their inability to digest simple milk formulae, which other infants can handle with the greatest ease. It is interesting to pursue this train of thought a little further in view of the epoch-marking investigations of Finkelstein, and other eminent investigators, into the phenomena of internal metabolism. The subject is too big to be discussed within the limits of this paper, but it is important to bear in mind the contention of this school, that diarrhoea is frequently the

result of conditions which have arisen in the internal metabolism. Pediatricists formerly were willing to explain diarrhoea as the result of the irritation of the mucous membrane of the bowel, by unsuitable food. Of course we must recognize certain foods as having a direct irritative action upon the mucosa, just as certain drugs act as purgatives, but Finkelstein has shown that there are possibilities of harm from changes which take place in the food products, after they have passed through the mucous membrane and are in fact in the blood and lymph stream. That there are metabolic errors, which react upon the mucous membrane and which may be the cause of marked pathological changes in the mucosa, has followed naturally upon the studies of this school. While we cannot wholly endorse their claims that many diarrhoeas are due entirely to these metabolic changes and that bacteria play only a minor and secondary part in the etiology of diarrhoea, yet we must acknowledge that their study has awakened a new interest and offers very alluring prospects of valuable results to be accomplished along this side line.

The therapeutics of irritative diarrhoea includes then the medicinal handling of the diarrhoea and the rearrangement of the dietary in consonance therewith. If the food is unmistakably unsuited to the child it must of course be stopped. The diarrhoea will cease as soon as the offending material has been eliminated, for this, a simple purgative must be used, castor oil is best if it can be retained; if there is much nausea and the tongue is badly coated, minute doses of calomel and soda, given dry if necessary; if there is much acidity in the vomited matter or in the stool, milk of magnesia until the offending material is eliminated. It may be necessary to use enemata to prevent the peristaltic wave from reversing itself and so producing vomiting. A weak mustard paste applied to the epigastrium is often of service and occasionally it may be necessary to use adrenalin or cocaine solution, to quiet the stomach enough to retain the purgative medicine.

The green apple diarrhoea is an extreme example of this type of disorder. Immediate purgation is the only rational treatment for such cases and complete stoppage of that kind of food. When, however, the indigestion is of some essential element of the food, such as milk, then the same treatment is indicated, but one can keep the child off milk for only a limited time and a return to milk feeding must be made gradually, according to the tolerance of the child. According to Czerny and Keller the different elements of the milk, the fat, the proteid, and the sugar, may be either the exciting cause of injury to the intestine or a cause of deranged metabolism. I can

*Read before the Kentucky State Medical Association, Louisville, Thursday, October 31, 1912.

only refer the student to recent discussion of the problem of milk feeding, for information along this line of the causes of diarrhoea.

Infective types of diarrhoea postulate the generally accepted doctrine of the relationship of bacteria to inflammation. For practical purposes one may divide these diarrhoeas under three heads, the catarrhal, the ulcerative and the toxic. The catarrhal type is analogous to the passage of large quantities of mucus from the nasal and bronchial mucous membrane. The mucus, here, however, must be more or less mixed with other materials, which are thrown out into the intestinal tract, so that it is of different colors, green, yellow, brown, etc.; of varying consistency, thin, thick, ropy, tenacious, etc.; mingled with food products in varying stages of digestion, with normal or abnormal secretions from the glands which empty into the intestine, and all scented with diverse putrefactive or fermentative changes in the food or the secretions. It is a moot point just now, as to whether bacteria are responsible for this condition. It may as well be acknowledged that no one has as yet found or isolated any organism which can be proven to be the cause of this clinical syndrome. The fact that it is most common in hot weather and in children who are upon cow's milk or a mixed diet and is especially frequent and malignant in infant asylums, where young children are grouped together, makes it most probable that a living organism is the cause of the disease, rather than some error in the fragmentation of its food. The fact that we have not as yet isolated the organism or organisms is simply negative and of very little value, as the same could have been said of tuberculosis before the discovery of its bacillus.

Mucus is an outpour from the mucous membrane and is partly a direct secretion of mucin and partly made up of dead epithelial cells, which have covered over the surface of the intestinal villi. This excessive formation of mucus is peculiar to children so that the term summer complaint is limited in its application to that early age. We know that this overproduction of mucin is peculiar to young people whose tissues contain relatively a larger proportion of mucin than adults' tissues. The epithelial cells are less mature, like the lymphatic glands, and therefore more liable to inflammations and disease. In infancy we have a mucous membrane more exudative of mucus, more easily injured by foreign bodies or by living organisms, a food which is given to the child in its raw state and containing great numbers of bacteria, and the summer heat and humidity to lower the resisting power and it is no wonder that so many of the little ones sicken and die. Certain of

these factors are remediable and certain are beyond our correction.

The mucous membrane of the jejunum and the upper part of the ileum is the portion of the bowel which is most affected in these catarrhal inflammations. It is irritated by food which is unsuitable, or the food may not be bad but at that time there are certain forms of bacteria multiplying in the bowel which grow best on that particular kind of food and produce out of it end products which are irritating to the mucosa. Or the germs themselves may exert a locally irritating effect upon the bowel. Or the digestive functions may be in such abeyance that the food is fragmented into unusual and bizarre radicals, which will inflame the membrane.

Let us take up these items seriatim—the heat and humidity, the bacteria, the food and the viable mucous membrane.

The heat and humidity can be controlled to some extent by electric fans, ice water, or wet cloths hung in a draft. We all have seen the quick results of a cool day following a heated term, or a cool boat ride on river or ocean. Heat depression is easier to feel than to measure by scientific apparatus.

The bacteria may be divided into two great classes, the proteolytic and the fermentative. The proteolytic develop upon nutrient media of nitrogenous nature. When nitrogenous matter undergoes decomposition poisonous products, ptomaines, etc., are formed, and foul gases and putrid stools are met with. There is absorption of toxic materials which increase the temperature, the restlessness, and the prostration; according to the character of toxin elaborated we find one or another symptom predominating. We do not know enough about the bacteria of putrefaction and the chemical compounds formed. But we can diminish the number of bacteria by active purgation, preferably with oil or calomel, and remove millions of germs in this way. We can possibly limit their activities, inhibit their growth, if we do not entirely kill them by various antiseptic drugs. We can give a carbohydrate food which will not be a suitable nutrient medium for them and which will form acid products which are hostile to the proteolytic bacteria, as they grow best in an alkaline reaction of the bowel. We can, by tea or tannic acid in its organic combinations, form insoluble tannates of the alkaloids generated out of nitrogenous matter. When the stools are foul and offensive, we should give such antiseptics as will lessen bacterial action, after having flushed the bowel. Bismuth subnitrate, or other bismuth salts are the most reliable. The sulpho-carbolates of sodium calcium and zinc are probably equally reliable. They should be given in dose enough. The bismuth salts are best administered in ten

grain doses every two hours, until the stools show black. When that object is attained bismuth has accomplished all that it can. Of the innumerable antiseptics recommended and poured out upon a gullible people one must always bear in mind that nothing should be administered which will in any way hinder normal digestion in the stomach or intestine. The fermentative bacteria grow on carbohydrates and produce various acids, which cause a watery, acid diarrhoea, frequently foamy or spurty, and yellowish or watery in color or consistency. There is often much colic and gas, but unless other conditions are grafted upon it, there is little danger. The fermentative bacteria grow upon carbohydrates, barley water, sugar of milk or other sugars. When the carbohydrate content of food is much increased the colon bacillus becomes a facultative fermentative bacterium and its toxicity lessened. The character of food then will help determine the flora of the intestinal tract and one must apply a full knowledge of dietetics in such cases. In general, acid stools indicate fermentative bacteria at work, so that albuminous foods are to be given, such as egg albumen, beef juice, etc. But when the stools are offensive, then the carbohydrates, such as barley, rice or oatmeal water, grape juice, etc., should be given. Soups and broths really contain very little besides extractives, and the meat jellies, like chicken jelly, contain gelatin, which is not attacked by bacteria and which is therefore a fine food under these conditions, being a proteid sparer and yet not being decomposed itself by organisms.

Milk which contains so many different kinds of food and often so many bacteria is contraindicated in diarrhoea. And frequently one will find that an intolerance of milk established at such times, will persist for many days if not weeks. It is often advisable to add condensed milk to barley water or other cereal decoction, and when it is tolerated, then skimmed milk, in small amounts, may be slowly added and increased. One often sees large curds of milk passed from the bowel with much aggravation of the symptoms, because the curds have carried infection and irritation through the whole length of the intestine.

The mucous membrane itself will require a therapeutics adapted to the condition present. In catarrhal inflammation of the mucosa of the small bowel, we shall find there is an outpouring of mucus and a loss of the cells covering the villi. As the epithelial cells are destroyed, their places are filled by other epithelial cells, which are less perfectly mature and thus less able to do their functions properly. These functions in brief are the absorption of the food products which must pass through these cells before they can reach the blood

vessels and lacteals and which food products, as we know from our physiology, are largely recombined and synthesized by the epithelial cells. Secondly they protect the tissues of the villus from the actions of irritative toxins or enzymes in the intestinal canal, and thirdly they must preserve their own integrity of structure and live out their own cell life process. The immature cell is far more likely to break down under the attacks of the toxic material within the bowel, and therefore when a catarrhal condition is once started it continues under less and less provocation and this explains why the mucus persists in stools so long after the original disease is apparently cured. The nutrition of children suffering from this catarrhal trouble is often seriously interfered with, because of the inability of these epithelial cells to perform their functions properly, and therefore it is exceedingly important to watch the diet closely for days after recovery. The accepted drug treatment of this inflamed membrane is with bismuth or other similar preparation. At present we cannot offer any suggestion of a better treatment, but the postmortem pictures contained in textbooks of the mucous membrane of the intestine practically covered with the black compound of bismuth, will show that even it fails very largely of attaining the result we desire. Milk of bismuth is better than the other salts in many such cases, because it does not have the crystalline formation of the other compounds, for the crystals themselves are often irritating to the inflamed mucous membrane.

The ulcerative type of enteric disorder has for its seat principally the mucous membrane of the colon, and is due to the action of various organisms, either locally or through their toxins. There are a number of bacteria which have been recognized as causing ulcerative changes, such as the bacillus dysenteriae, the streptococci and others. The ulcerative type of diarrhoea is characterized by frequent small stools of mucus and blood. There are tenesmus and tormina, the temperature is not much elevated as a rule, the prostration is very pronounced. In a previous editorial the writer has gone very fully into the rationale of the treatment, but will here take time only to summarize the facts. The bacillus of Flexner elaborates toxins in the small bowel. Neither the bacillus nor the toxins seem to attack the mucous membrane at that point, but the toxins are observed passing through the liver into the general circulation and are eliminated through the mucous membrane of the colon; where a portion of the toxin ulcerates the most superficial part of the valvulae conniventes. Another portion of the toxin attacks the nervous system and produces convulsions and death. The treatment then consists in the removal and destruction of the ba-

cillus and toxins within the small bowel. This is best accomplished by purgation with small doses of castor oil and aromatic syrup of rhubarb, alternating with one-hundredth grain doses of bichloride or biniodide of mercury, every two hours. The treatment of the ulcers in the colon, whether due to the bacillus or to the streptococci, is best by colon douches of mild demulcent solution and by warm counter irritation over the abdomen, and by the administration of small doses of opium, which should be given until physiological rest is secured. But opium should never be continued if the bacteria are still at work in the intestine or when its administration is followed by a rise in fever or an increase of foul odor to the stools. It has seemed to the writer to give better results when prescribed with small doses of aromatic sulphuric acid.

The toxemic type of diarrhoea is shown by frequent vomiting and purging of colorless and practically colorless liquid from the bowel. The internal temperature is very high, hands, feet, face and breath may be cold, the eyes sunken and heart beat feeble and pulse almost gone. After death there is little if any evidences of any pathological change in the intestine. Cholera infantum kills by action of its toxins; these toxins are frequently formed in the food before it is ingested. There is a potentiality of such toxin in all proteid foods. Vaughn for instance has demonstrated it in egg and other types of albumin. This form of diarrhoea is comparatively rare in recent years, because we know so much better how to take care of milk and other foods for children. Such toxic decomposition of products have largely been eliminated by education of the dairy-men and likewise of the public. The fatality results from the enormous loss of liquid and it is necessary for us to maintain the strength of the patient and the liquid content of the blood, until such time as enables nature to secure another readjustment of the equilibrium. Such cases require hypodermies of small amounts of morphine and atropine; the administration of water by mouth, if practicable, otherwise by enteroclysis, according to the Murphy method or even by hypodermoclysis. We must play for time, because the elimination of the poison is rapid and if we can maintain life for a few hours the victory will be ours, and little other medication will be needed. It is important not to make the mistake of diagnosing every case of slight vomiting and purgation as true cholera infantum. Most cases of diarrhoeal disorders, in very young children, will begin with more or less vomiting and purging. It would be very bad therapy to use opium in such cases, for it would lock up in the bowel the very substance which was causing the

trouble and therefore prolong the attack. The characteristic feature of cholera infantum is the persistent vomiting and purging of the odorless, non-fecal liquid, with exceedingly rapid prostration, and in only such cases is morphine and atropine allowed.

THE TRUTH ABOUT MEDICINES

This department presents, in concise form, facts about the composition, quality and value of medicine. Under "Reliable Medicines" appear brief descriptions of the articles found eligible by the A. M. A., Council on Pharmacy and Chemistry for inclusion with "New and Non-official Remedies." Under "Reform in Medicines" appear matters, tending toward honesty in medicines and rational therapeutics, particularly the reports of the A. M. A. Council on Pharmacy and Chemistry and of the Chemical Laboratory.

The text on which these abstracts are based may be obtained from the American Medical Association, 535 Dearborn Avenue, Chicago.*

THE FOOD AND DRUGS ACT AMENDED.—About a year ago the Supreme Court decided that the Food and Drugs Act of 1906 contained no prohibition against false statements as to therapeutic value. Now Congress has amended the law by adopting Congressman Sherley's amendment which makes therapeutic lies on the label of a medicine illegal by adding the following as paragraph 3 to Section 8, "If the package or label shall bear or contain any statement, design, or device regarding the curative or therapeutic effect of such article, or any of the ingredients or substances contained therein, which is false and fraudulent." There can be no question as to the intent of this amendment. It says to the "patent-medicine" faker in plain and unequivocal terms: "Thou shalt not lie."—*Jour. A. M. A.*, Aug. 31, 1912, p. 727.

VIBURNUM COMPOUNDS AND OTHER NOSTRUMS.—There are a number of drugs which have in some way obtained a reputation as being valuable in the treatment of diseases of women without their therapeutic claims ever having been proven. A considerable number are combined in various nostrums (sometimes with therapeutically active drugs) and exploited for the cure of female disorders. Thus Hayden's Viburnum Compound is claimed to contain American skullcap (*Scutellaria lateriflora*), cramp-bark (*Viburnum opulus*) and wild yam (*Dioscorea villosa*). Other mixtures of this kind including "patent medicines," proprietary nostrums and "pharmaceutical specialties" contain such drugs as black cohosh, blue cohosh, goldenseal, lady's slipper, false unicorn-root, cramp-bark, wild yam,

star-grass, trailing arbutus, motherwort, Jamaica dogwood, pulsatilla, squaw-vine and saw palmetto. The popularity of preparations of this kind is purely an artificially created one. A nostrum containing, let us say, extractives of some little-used or worthless drugs is put on the market and heavily advertised. Should it be advertised in a manner to make it sell, a host of imitations appear and the large pharmaceutical houses put out substitutes for it. The uncritical physician does the rest. He prescribes it indiscriminately in the class of cases for which it is advertised. Naturally a certain proportion of the patients who take it recover, and the recoveries are credited to the nostrum. A vicious circle is thus established and the demand for the stuff increases. Its sale, and the sale of similar products, continues until the overwhelming experience of those who have prescribed it proves its uselessness. In the meantime the manufacturers have reaped a harvest at the expense both of the public and of the medical profession. And the manufacturers' excuse for putting such "specialties" on the market is that physicians prescribe them.—*Jour. A. M. A.*, Aug. 31, 1912, p. 735.

MISSOURI PROGRESSIVE.—At the annual meeting of the Missouri Medical Association the following motion, urging its members not to support medical journals which carry questionable advertising was adopted:

Whereas, The American Medical Association has been doing effective work to counteract the influence of certain medical journals whose advertising pages carry many fraudulent advertisements; therefore, be it

Resolved, That it is derogatory to the best interests of the Missouri State Medical Association for members to publish articles or papers in medical journals which are not in sympathy with the purposes of this organization; and further

Resolved, That members are hereby requested to cease publishing original articles or other matter in journals whose advertising pages contain fraudulent and questionable advertisements and to give loyal and constant support to the Journal of the Missouri State Medical Association.—*Jour. A. M. A.*, Aug. 31, 1912, p. 735.

THE HABITINA FRAUD.—The promoters of habitina, R. C. Prewitt and Rayland C. Bruce, constituting the Delta Chemical Company, were fined \$2,000 and sentenced to five years at hard labor in the United State penitentiary. Habitina was one of those vicious mix-

tures containing large amounts of morphine which are sold to drug addicts but which instead of curing substitute slavery to a high-priced, fancy-named, morphine mixture for that of which the simple opiate itself. In summing up the case the post-office inspectors, in their report, concluded as follows: "The conviction obtained in this case has terminated one of the most pernicious and outrageous frauds ever perpetrated on a credulous public, who were not only defrauded out of large sums were made maniacs—how many died under \$2,000 each, but were robbed of health of body and mind; some were rendered blind and some were made maniacs—how many died under the 'treatment' will never be known—but, taking their own testimonials as a source of information, four out of eight have died drug addicts, and out of the thousands of persons they have treated but one witness could be produced by the defendants to testify in behalf of this drug having any remedial properties whatever. These defendants deliberately fostered the most dreadful forms of drug slavery for their personal gain. They made no effort to cure the patient for the blood money thus obtained. They produced no evidence which would traverse the contention of the Government that the whole purpose of the defendants was to substitute for the slavery to the drug purchased by the habitue from the 'corner pharmacist' under the restrictions of state law, the slavery to the same and worse drugs purchased under a disguised name at many times a fair commercial price from the Delta Chemical Co."—*Jour. A. M. A.*, Sept. 7, 1912, p. 817.

NEWS ITEMS AND COMMENTS

The Burley Tobacco Society has purchased the property recently, for many years used by Dr. Sprague as a Sanatorium, for the treatment of mental and nervous diseases and liquor and drug addictions in Lexington. Dr. Sprague will not give possession, however, until late in the spring of 1913, at which time his new buildings on the Harrodsburg pike, just outside of the city limits, will be completed and occupied. The profession of the State will be glad to know that High Oaks is to be improved over its past high standard.

THE ADAMS-STOKES SYNDROME.

(REPORT OF A CASE.)

By HENRY ENOS TULEY, Louisville.

The term Adams-Stokes disease was given by Houchard to a remarkable syndrome first described by Robert Adams of Dublin in 1827, by Wm. Stokes, who reported four cases. In Germany His and Hoffman, in France Houchard and Charcot, in this country Prentiss, Osler, Stengel and others have described the condition. This syndrome or heart block is an association of an intense bradycardia, vertigo, dizziness, nausea, syncope or epileptiform seizures.

It was formerly thought to be found only in patients of advanced years, but the literature shows a large number of young adults, below forty years of age.

Until comparatively recent years the etiology and pathology of this syndrome have been obscure, it being ascribed to fatty or fibroid degeneration of the heart, diseases of or injuries to the medulla, arteriosclerosis, especially affecting the coronary arteries and syphilis. Until careful dissection of the heart in connection with physiologic experiments was made by Kent in 1893 it was not known that a fibrosis of the bundle of His was present in practically every case, and the consensus of opinion to-day is that this degeneration is uniformly present in all cases.

The bundle of His is a small muscle 18 m.m. long, 2.5 m.m. broad, and 1.5 m.m. thick connecting the auricles with the ventricles. The auriculoventricular bundle is the essential or-

gan of conduction; the auriculoventricular impulses pass through this muscle starting in the auricles and passing over into the ventricles causing them to contract. The destruction of the bundle of His yields a uniform result, complete dissociation of the auricular and ventricular rhythms.

The experiments of Kent and His, confirmed by later investigators led to the conclusion:

(1) That the slow pulse of Adams-Stokes disease was due to dissociation between auricles and ventricles (heart block) and to the slow independent rhythm of the ventricles.

(2) That the syncopal attacks (Adams-Stokes syndrome) were due to the cessation of ventricular beat but not of the auricular beat*.

The symptoms are so uniformly characteristic as to be grouped under three heads: (1) the intense bradycardia, (2) the vertigo, syncope or epileptiform convulsions, (3) the dyspnea and pain present in the precordial region or below.

The pulse is uniformly slow, frequently falling to 20 per minute or below. Halbertson reports a case showing a pulse of 5 to the minute. The pulse usually is of high tension, between 150 and 180. The arterial tension, dyspnea and pain may be relieved by suitable medication but the bradycardia persists in spite of all remedial measures. The frequency is not increased by exertion of any kind.

Auscultation may show a faint systolic murmur, but usually none. There may be a visible pulsation in the right internal jugular vein inside the clavicle indicating auri-

*Hirschfelder: Diseases of the Heart and Aorta; Lippincott.

cular contractions that do not pass to the ventricles.

The vertigo may precede the bradycardia by a number of months becoming more pronounced, accompanied by syncope or mild epileptiform convulsions with one onset of the severe bradycardia. The skin is of an ashen pallor at the beginning of the syncope. Barr*, has noted that convulsions occurred when the pulse disappeared for 20 seconds.

The dyspnea may be severe and one of the most prominent of the subjective symptoms. This is usually accompanied by the precordial pain which is more or less a constant symptom.

The diagnosis of this condition should be easy, the syndrome described is so characteristic, but as in the case to be described other symptoms may so outweigh the syndrome as to focus attention to other possible conditions and lead the diagnostician astray.

Repeated syncope attacks, with or without marked bradycardia, should be a warning signal of the possible pathologic condition and the first evidence of bradycardia should make the diagnosis possible.

The prognosis is extremely grave. Cases have been reported as surviving for several years, but as in true angina pectoris a fatal termination is inevitable.

Hirschfelder* emphasizes the fact that complete heart block and Adams-Stokes syndrome are by no means synonyms; the former represents merely the dissociation of rhythms, while the Adams-Stokes syndrome brought on by cerebral anemia during ventricular stoppage is a totally different matter, and that heart block may persist for months or years without occurrence of the syndrome.

The Adams-Stokes syndrome may be present not only in the initial and not in the later stages of the heart block.

J. B., an attorney in Louisville on legal business, having driven himself most of the way in an automobile from Washington over the mountains and through the Shenandoah Valley.

The early life of this man was a very strenuous athletic one, and he was rated a splendid physical specimen. Meeting with domestic difficulties he lost his grip upon himself, drifted from bad to worse, finally landing in the Capitol where he became a motor-man, during which time he suffered a fractured leg. Recovering from this he took the civil service examination for a legal position in the Attorney General's office, applied himself very strenuously to his work, for several years, later severing his connection with the

department and assumed a number of intricate and important private legal cases which gave him but little rest or recreation. He was usually so wearied before his trip west, as to find it impossible to walk from his office to his residence, less than one quarter of a mile. I mention this as having some bearing on his subsequent history.

Soon after his arrival in Louisville his wife was taken quite seriously ill and added to this worry he plunged into the midst of depositions which kept him up at night. His work finished here he planned to leave for Chicago on July 2nd. On June 30th when about dressed for a dinner engagement he became very dizzy, things grew black and he fell on the bed unconscious and in collapse. I saw him within fifteen minutes, he had regained consciousness but was bathed in a profuse sweat. His heart's action was very slow, his pulse at times imperceptible, he was pallid, with considerable dyspnea, and complained of agonizing pain over the heart. A hypodermic of nitroglycerine, 1-100 grain, was given at once, with rapid improvement in every way. He was shortly afterward given 1-200 grain atropine for the leaky skin with beneficial results.

I left him comfortable in about an hour with an improvement in all symptoms. His wife was given some nitrite of amyl pearls for use in case of a recurrence of the symptoms. At five o'clock the next morning I was recalled hurriedly. He had slept well until a little before 5 o'clock, when his wife was awakened by his stertorous breathing. Hurrying to his side she found him ashen in color, no pulse to be felt, eyes rolled back with every appearance that he was dying. She gave him an inhalation of nitrite of amyl and called me. He had just recovered consciousness when I arrived. He complained of agonizing pain at the pit of the stomach, his pulse was 34, with no volume, but this slowly improved under a hypodermic of nitroglycerine, however much more slowly than the evening before. When he could talk he told of going to the toilet for a bowel movement, a sudden attack of vertigo came on with nausea, and he had difficulty in getting to bed, not knowing whether he had gotten to it or not. His temperature was subnormal by mouth.

At noon his temperature was 100 by rectum, his pulse 34 to 36 with much better volume. He still complained of severe pain over the pit of the stomach, was very tender below the ensiform and there was quite perceptible rigidity of the upper abdominal muscles. He had vomited a number of times a dark bitter fluid. So prominent were the symptoms referable to the upper abdomen, they so far outweighing the condition of the heart with the rise in temperature, it was believed that

*Mackenzie: Diseases of the Heart. Oxford University Press.

*Loc cit.

might be an acute surgical condition developed in this region, in spite of the bradycardia. He was seen at this time by Dr. Frank in consultation, who concurred in the opinion there might be an acute surgical condition in the region of the pancreas and advised his removal to the infirmary for closer observation. This was done by 3 p. m. He was very thirsty and drank large quantities of water which was soon vomited, until it was withheld entirely, and saline administered per rectum. His pulse remained at 36 per minute, and his pain under a hypodermic of 1-4 morphia before leaving the hotel was considerably improved.

At 7 p. m. he was seized with vomiting followed immediately by stertorous breathing, loss of pulse at the wrist entirely, which shortly before had been beating 24 times per minute. Oxygen and nitroglycerine were administered, artificial respiration continued for some time, with gradual return of consciousness, still complaining of pain below the ensiform. Between this and 9 o'clock he slept some, gradually growing more restless. At 9:05 he waved his hand to his wife and called to her he was all right, at 9:10 became very restless, gagged and retched violently, raised on his elbow, fell back rigid, breathed two or three times, and expired.

Consent was readily had to an autopsy, which was performed by Dr. Baldauf. The upper abdomen was first explored, with the following findings: a normal pancreas, much enlarged and congested liver and spleen, stomach contracted, kidneys and bowels normal. On opening the thorax a greatly enlarged heart presented, the pericardium was distended with fluid, the heart muscle was pale, and on gross examination an area was found with appearance of a gumma.

A closer examination was made of the heart by Mr. Wallace Frank under the supervision of Dr. Baldauf which revealed a fibrosis of the interventricular septum especially marked in the region of the bundle of His and a fibrosis of the papillary muscles. In one place in the heart wall there was what appeared to be on macroscopic examination a gumma. Heart valves were slightly sclerotic especially the semilunaris, the mitral and tricuspid. Ascending branch of aorta showed atheromatous plaques.

DISCUSSION.

Leon K. Baldauf: In the specimen I have brought here to-night a number of gummata are found in the wall of the left ventricle and beneath the endocardium in the intraventricular septum. The bundle of His was dissected out. As it passed in, it simply merged with this thickened, sclerotic area in the wall which separated the right from the left ventricle. Sections made of this area, which before the heart had been

fixed was distinctly elevated above the surrounding tissue, show a typical picture of gumma.

It is sometimes very difficult to make diagnosis of gumma of the heart. Loomis, of New York, who has done probably as good work as any one along the line of the histology of gumma of the heart, lays down three points for guidance in making the diagnosis. First, there must be definite cellular infiltration; second, there must be definite necrosis, and, third, there must be a marked endoarteritis. Sections of this heart show all three conditions. There is definite rounded infiltration with increase of young connective tissue; there is distinct necrosis of the cells and marked endoarteritis. In many areas there can be distinctly made out what are apparently giant cells, but I think these are nothing more than obliterated blood vessels.

I have brought here to-night, for purposes of comparison, two ox-hearts. I think the bundle of His was first demonstrated in the heart of a frog, but in a heart of this size it can be more distinctly demonstrated. In a recent article based on experiments carried out under Dr. White, at Harvard Medical School, the statement is made that the fibers composing the bundle of His have their origin in both auricles, but a large number of these fibers start in the superior vena cava. The coronary sinus reticulum merges with the main bundle of His. This main bundle passes through the wall of the intraventricular septum and gives off branches, one division being the right septo and the other the left septo.

J. Rowan Morrison: This is one of the most interesting papers that has been presented to this society for a long time, and Dr. Baldauf has given us a most beautiful demonstration of the bundle of His in a beef heart as compared with the human heart. As he stated, this bundle is very difficult to trace in the human heart, but in the beef heart it is comparatively easy. This bundle has to do with one of the most important functions of the heart action; namely, conductivity. According to Mckenzie, who has studied this bundle very thoroughly, these fibers start where the vena cava goes into the auricles, at what is called the Keith-Flack node. Then it extends down into the auricular ventricular septum, and from there into the ventricle, where it divides into the right and left branches. Erlöveer has demonstrated, in experiments on dogs, that by compressing the bundle of His, a certain amount of heart block could be produced. To understand this we must remember that the impulse begins in the auricle, which contracts first, and it is then transmitted through the bundle of His to the ventricle. Therefore, a certain amount of compression of these fibers will produce a proportionate amount of heart block. In other words, Erlöveer has found that the normal number of ventricular contractions is between 23 and 28 per minute and, as Dr. Hirschfelder has

pointed out, one may have complete heart-block without having the Stokes-Adams syndrome. This syndrome comes in where there has been enough contraction to allow a very slow ventricular contraction. In other words, there is not enough blood sent to the vital centers of the brain to nourish them properly, and as a result of this faulty nutrition, epileptiform convulsions and similar symptoms occur, and at the same time we notice that the jugular pulsation is out of proportion to the apex beat, or to the radial or brachial pulses. In heart blocks there is usually a definite ratio, sometimes 1-2, 1-3, or 1-4, whereas in auricular fibrillation we find pulsations that do not have any definite relationship.

It has also been brought out that we may have a slowing both of the auricular and ventricular contractions, as in cases of prolonged bradycardia, and these patients seldom or never develop the Stokes-Adams syndrome. These cases are the ones that live a long time.

In regard to the effect of heart block, many of these cases, where there is not a complete block, may live a long time, but when the Stokes-Adams syndrome develops, the patient will sooner or later suffer attacks of angina pectoris, which is usually followed by death in a comparatively short time.

Another interesting point is pain in the epigastrium produced by heart conditions, as evidenced by the condition of angina associated with Dr. Tuley's case. Neusser, in his monographs on angina pectoris, gives a description of angina quite different from that usually described in medical societies by local observers in times past. I have heard competent observers say that one attack of angina pectoris was almost sure to have a fatal termination, and that no one ever survived three attacks, whereas in this article Neusser says that these patients may live a long time, and that the manifestations may be in very distant parts of the body; for instance, through the vagus and the sympathetic nerve, pains may be manifested about the jaw and head. A number of his cases were supposed to be due to gallstones, and some to kidney stones. In some instances the pains were manifested in the lower extremities, the testicles and even the feet, showing how conditions of the heart, through the vagus and sympathetic nerves, may cause pains to be manifested in regions quite distant from the heart itself.

F. C. Askenstedt: I have thoroughly enjoyed Dr. Tuley's paper.

A great many theories as to the cause of heart block have been advanced, but I believe the one promulgated by Mackenzie is the most original and the one that is generally accepted to-day. As Dr. Morrison mentioned, heart block and Stokes-Adams syndrome are not synonymous terms, but they are very intimately connected. Mackenzie attributes Stokes-Adams syndrome to sudden interruption of the impulses traveling

from the auricles to the ventricles. If we take a frog's heart, or the heart of any other animal, and ligate the bundle of His, or interrupt the continuity of the bundle of fibres in any way, we find that the ventricles suddenly stop. Sometimes they will remain at a standstill, but more often, after a certain length of time, they will assume a new rhythm; a rhythm of much slower beat. Mackenzie says that the same thing occurs in the human heart when the bundle of His is impinged upon by scar tissue (as in the specimen shown), as a result of a syphilitic gumma, or from arteriosclerosis, or from rheumatic infiltrations, which are the most frequent causes. The impulse is suddenly arrested and the ventricles cease their activity; syncope occurs, resulting from the anemia of the brain, accompanied by unconsciousness, vomiting and, frequently, convulsions.

This, I think, is the most logical explanation of these symptoms. However, these cases do not all present exactly the same symptomatology. Three cases have come under my observation either just before or during the attacks, and each one presented a little different picture. In one case the patient seemed perfectly well. While sweeping his store one morning he was suddenly seized with the Stokes-Adams syndrome, and after that his pulse was never found above 40, showing that the conductivity of the bundle of His had been interrupted. He had one more attack of Stokes-Adams syndrome after that, but he is living to-day, nine years after the first attack.

In another case the patient became unconscious while sitting in a chair, and fell to the floor. When he regained consciousness his pulse could not be felt at the wrist for some time. Finally, 18 to 20 per minute could be counted. He had ten or twelve of these attacks and finally developed complete heart block, running a pulse of 26. That was five years ago and he also is still living.

The third case I saw showed on polygraphic tracing a lengthened interval between the auricular and ventricular impulses, which indicates threatening heart block and Stokes-Adams syndrome, and he developed several of these seizures. I suppose he had 14 or 15 attacks in all. I saw him in two attacks, each lasting about three minutes; with slow, irregular pulse, imperceptible during unconsciousness; and after I left the house he died in a third attack a few minutes later.

One point that is particularly valuable to us as clinicians is that we may induce heart block, or Stokes-Adams syndrome by the administration of digitalis or strophanthus. A patient with a tendency to heart block, or, in other words, where the impulse is delayed as it travels from the auricles to the ventricles, will run serious risk from the administration of any remedy of the digitalis group. There are many e that will

stand immense doses of digitalis without danger while in others it must not be given. The reason for this is that digitalis and other members of that group, which stimulate the pneumogastric nerve, also impair the conductivity of the bundle of His, so that where there is already some delay of the impulse, the administration of this drug will further impair its transmission, thus inducing the Stokes-Adams syndrome, and the patient may die in one of these attacks. If the graphic method of examining the heart has accomplished nothing else, it has certainly served a good purpose in enabling us to better ascertain the condition of the bundle of His before administering digitalis.

Carl Weidner: I think I saw a good many cases of this kind years ago and did not know what they were. The subject is a comparatively recent one.

Dr. Tuley has given us a thorough resume of the subject and has brought out several points of interest. He says that the diagnosis is easy. Where we have a typical picture it is easy to make up our minds that we are dealing with the Stokes-Adams syndrome, but it seems to me that in many cases the symptoms are so illy defined as to give rise to considerable doubt. Last year I saw a man from another city, who had normally a very flushed red face. He gave a typical history of these attacks. He was a business man, and while walking about his store he would suddenly suffer an attack of vertigo of slight degree and then lose consciousness. This lasted only a few moments and his face would become very pale temporarily. After lying down for a while he would regain his normal condition and color. This man tells me that sometimes when he feels these attacks coming on, he has an inclination to walk. That is a very interesting feature to me.

Another point of interest is that we sometimes see symptoms of this kind in connection with organic diseases of the heart, in cases where the bundle of His is not directly affected by some disease, such as syphilis, or some infective process. In lesions of the valvular orifices, sclerosis, etc., I believe we may have involvement starting here, and extending deep enough to affect the bundle of His, producing, secondarily, the typical Stokes-Adams syndrome.

During the present year I had a very interesting case in which diagnosis was made of myocarditis complicated by nephritis, and I was positive that I had to deal with a pericardial effusion, which on five different occasions I tried to tap without results.

As to the administration of digitalis, if digitalis may cause partial heart-block, as is admitted by some authors, it teaches us one lesson; that in these cases it is a dangerous remedy, no matter whether the condition is purely neurotic or whether we have an organic disease of the bundle of His. Possibly it should be given in very

small doses, but I do not see any reason why we should give digitalis in any case where we have a very slow pulse—say 28 to 30. We might consider combining with it some other appropriate drug to offset the bad effects of the digitalis. However, it would be better in these cases to give some preparation which does not have a bad effect upon the bundle of His by lessening its power of conductivity.

SCIATICA AND TREATMENT.

By J. W. TURNER, Malott.

I have several reasons for selecting sciatica and treatment as my subject for this paper. One of them is that sciatica is the most frequent and severest form of neuritis that we are called upon to treat and usually considered the most stubborn to yield to treatment. Another was that this seemed especially so with me in my first years of practice, and that for the last few years I have been having better success than formerly with a very simple treatment.

Finally, so far as I know, this society has not had a paper on this subject. Sciatica is the most common and severest form of neuritis. It may be a functional neurosis or neuralgia. It occurs in adult males most frequently. In my practice the relative proportion of cases being as seven to three.

It very rarely occurs before the age of twenty and rarely after the age of sixty, though I have had a case in a young man only seventeen years of age and one old man over seventy. In my cases it occurred most frequently in the right limb.

Osler and some other writers say a history of rheumatism or gout is present in many cases, but I have never found either in my cases. I have often noticed persons exposed to cold, after muscular exertion, having an attack of sciatica, which acted, I think, as an exciting cause. Death from sciatica is rare if ever. I do not think we have any evidence as to the cause of the disease from an examination of the sciatic nerve after death. The very few cases that have been examined, either after death or in stretching of the nerve, give us very little information in a scientific sense. It does not show the real cause of sciatica. So I am free to admit that I do not know anything about the etiology of sciatica unless it is when we have a symptomatic or secondary sciatica, caused by pelvic tumors, pregnancy, enlargement of the retroperitoneal lymphatic glands or of accumulation of feces or foreign substances in the sigmoid flexure.

But this kind of cases has been so small with me that I doubt our having very many cases of symptomatic or secondary cases.

I am about ready to believe that we have

a specific cause for sciatica though I have no scientific reasons for so believing.

SYMPTOMS.

Pain is the most common and constant symptom. The character of the pain is sometimes described as burning and sometimes as a sensation of coldness. The patient feels as if a current of hot or cold liquid were flowing in the course of the afflicted nerve. At the beginning of the attack pain may be severe with or without fever, (generally without), but usually it comes on gradually and for a time there is only slight pain in the back of the thigh, particularly in certain positions or after exertion; soon the pain becomes more severe and extends along the course of the nerve even reaching down to the foot and radiating over the entire distribution of the nerve. Sometimes the pain is referred to circumscribed spaces which are tender on pressure. Painful and tender points in this affection are found in more or less of the following situations: on the sacrum, over the sacroiliac junction, at the sciatic notch, on the thigh along the curve of the nerve, in the popliteal space, over the fibula and on dorsum and outer portions of the sole of the foot.

The points situated at the sacroiliac junction behind the trochanter major and at the head of the fibula are most frequently the most painful and tender. Pressure with the finger upon some of those tender points may not only be very painful but excite a paroxysm of pain extending to other parts in the course of the affected nerve. The intensity of the pain varies much in different cases. The movements of the affected limb in some cases, occasion such an amount of suffering that the patient remains in bed keeping the limb as quiet as possible. In other cases the patient is able to walk but with more or less difficulty, pain being felt especially when the weight of the body falls upon the affected limb, and relief is found in the use of a cane.

In the first twenty years of my experience with sciatica I found the duration and course extremely variable and, as a rule, an obstinate affection, lasting for months or even, with slight remissions, for years. Relapses are not uncommon and the disease relieved in one nerve only appears in the other.

In the severe forms the patient becomes bed-ridden, and such cases were the most distressing and trying that I have been called upon to treat. The diagnosis of sciatica involves its discrimination from muscular rheumatism, and from affections of the hip joint. Muscular rheumatism, here as in other situations, differs from sciatica in the limitation of pain to the affected muscles, in diffus-

ion of tenderness over a considerable space, namely, a space corresponding to the muscles affected, and in the fact that paroxysms of pain are excited exclusively by movements of the muscles affected. Hip joint affections are distinguished by the pain in the hip being produced by pressure upon the great trochanter and by flexion and extension of the thigh. Then we would have more fever and general debility with the local symptoms, pointing to the existence of inflammation within the joint.

TREATMENT.

When I began the practice of medicine I treated cases of sciatica with the general treatment laid down in the text books that I had. I began with the idea that sciatica was a constitutional disease, either syphilis, rheumatism, tuberculosis or something of the kind. I gave my patients calomel and salts, followed up with iodide of potash, or sulphate of quinine, or if I had a rheumatic suspect I would give the salicylates as long as the patient could stand to take them. To some I gave strychnine and to some I gave Fowler's solution or arsenic and different preparations of iron. To some others, during an attack, I would give all of these drugs. To relieve pain I have given all forms of opiates internally and hypodermically. I have used morphine, atropine, as well as cocaine; I have tried antipyrine and acetanilid—all these and more could be named with only temporary relief. Locally, I have blistered; used counter irritants of most every kind such as chloroform, turpentine, etc., and every kind of hot applications, even hot lime poultices. I have never used deep injections of alcohol or chloroform or the galvanic current.

This was my routine for twenty years and was very unsatisfactory to me and to my patients, and during that time I treated fifty of them.

It is true that none of them died outright, but some of them thought they would and some said they did not care how soon they did if they had to continue to suffer so much. All of them were slow in recovering: none of the fifty were able to work under six weeks and the majority were incapacitated for months and one or two for years, while several were bedridden and practically helpless.

I am very glad to say that during the last six years my sciatic patients (and I have had twenty-seven in that time) do not have to suffer so long from the beginning of the treatment that I now use. They are up and able to work in ten or twelve days. I have had no relapses or remissions except in two cases and both of these quit taking the

medicine without advice but when they resumed the treatment as directed they were able to work in another week.

I will give a report of three cases treated as I have been treating sciatica for the six years mentioned. The final results of all of the last twenty-seven cases practically parallel these reports.

CASE I.

Mrs. M. A., age 32; mother of four children; of nervous temperament and never robust; mother died of tuberculosis; father living and in good health. I was called on May 19th, 1908, on account of pain in the back and right limb. I found her without fever, pulse 80, no appetite, constipated, urine high colored and scanty, feet and legs slightly swollen; she kept her bed most of the time on account of the pain. On examination I learned that she was pregnant (six months) and thinking that was possibly the cause of her discomfort I did not examine the leg very closely and failed to make a correct diagnosis. I gave her a laxative, some lithia tablets and strychnine sulphate gr. 1-60 every four hours, and instructed her to call me in a few days if no improvement was obtained.

May 22nd, I was called again. The laxative had acted satisfactorily, kidneys acting better, still no fever, no appetite and unable to sleep on account of the pain in the right leg. This was so severe that she frequently would get up with assistance in order to change the position, but could not bear any weight on it. After a closer examination I made a diagnosis of sciatica. I had never used this treatment on a pregnant case but not wishing to use opiates to relieve the pain and as she had already used hot applications without any relief, I decided to try the same treatment I had been using with success in other cases. I put her on powdered guaiac gr. 5, every three hours for twenty-four hours then every four hours for three days. The first night she slept fairly well and in four days she was able to be up with but little discomfort in the leg, and appetite was much improved. She continued her medicine every four hours until June 1st, when I discharged her as completely cured, as she was able to be up and go about her work without pain; had a good appetite, bowels regular and the swelling was gone out of her feet and legs. She was able to be up the last months of her pregnancy and was delivered of a fine, healthy baby girl in August. This is the only pregnant patient having sciatica that I have ever treated, and I don't think that condition had any connection with her sciatica.

CASE II.

Mr. R. A. P., age 61, farmer. Family history and previous health good. Making his

own diagnosis of his case on March 17th, he telephoned me to send him some medicine for rheumatism. I sent him six 1-2 grain tablets of calomel to be followed by salts and twenty 5 grain capsules of sodium salicylate to be taken every three hours with a glass of water.

On the 18th, I went away from home and was gone three weeks. During my absence my patient grew worse and as the medicine did not do him any good, he decided to treat himself. He took poke-root in whisky internally and treated the affected limb with all kinds of hot applications such as cloths wrung out of hot water, hot poultices, Sloan's liniment, etc.

This kind of treatment he kept up until May 1st, getting worse all the time. At this time he sent for me to come and see him. I found him suffering with agonizing pain along the course of the right sciatic nerve, the usual tender points on pressure with fingers, neither able to walk or stay in bed without pain, not sleeping much at night, having to get up and change position to get some relief then back to bed again; his pulse was eighty-five, no fever, not much appetite, constipated, urine high colored and scanty.

There being no symptoms of rheumatism of any kind, I diagnosed the case sciatica and so informed my patient and I also told him I thought he would be up and well in a week.

TREATMENT.

As the patient was constipated I first gave him epsom salts, teaspoonful doses every four hours until his bowels moved and put him on powdered gum guaiac every three hours for twenty-four hours, then every three hours just through the day time with as much as a table glass of water, with each dose. The second night he slept all night only getting up once and that to urinate; by the fourth day he could walk around the room with very little pain, sleeping well and appetite better, bowels moving without purgatives. The patient continued improving and by the tenth day of May was going around everywhere without any pain whatever, so I dismissed him as cured and he has remained so since.

CASE III.

Mr. L. H., age 24, married, strong and robust looking; family history very good. Came to see me limping and walking with a cane, on June 2nd, with the following description of his case: Sometime in the spring (April he said) while he was grubbing, his back began to hurt. He thought it was due to the kind of work he was doing, but later on it gradually began to hurt in the hip and down the right leg. He said he thought it was rheumatism then, but still tried to work, but on account of the pain finally had to quit.

I found him with no fever, pulse good, bowels regular, appetite fairly good but on examination of the affected limb, was able to trace the sciatic nerve the full course with my fingers, it being tender almost the entire course. Diagnosis, sciatica. I gave him thirty 5 grain capsules of powdered guaiacum to be taken one every four hours through the day with a glass of water with each dose.

He returned in one week entirely free from pain and could walk as well as ever. He was dismissed and has been at hard work ever since with no return of the trouble.

These cases serve to illustrate the plan I have followed and the results secured. I have no explanation to offer as to the action of guaiac in these conditions but I submit the effect has been, at least, satisfactory.

DISCUSSION.

S. E. Woody: In regard to the use of iodid and salicylic acid in the treatment of sciatica, I would suggest to the essayist that he use some one of the preparations of iodid and salicylic acid which are insoluble in acid menstrum, pass through the stomach unaltered and dissolve slowly in the alkaline secretions of the intestinal canal. There are various preparations of this kind which are well known, and so satisfactory are they that I have not used any soluble iodides for several years. As a result none of my patients ever complain of gastric irritation, and still the good effects are most pronounced.

J. T. Windell: As the essayist has stated, the etiology of this condition is rather obscure in a great many cases. In my practice I encounter quite a number of cases with pain in the region of the sciatic nerve which is a referred condition from a chronic posterior urethritis, generally of gonorrheal origin. I had a patient in my office this afternoon who gave a typical description of the pain of sciatica, and his trouble is due solely to a neglected gonorrhea.

J. G. Carpenter: To me this is a most interesting as well as a painful subject. I am just over an attack of sciatica. I walk with a big stick—not to hold the sciatica down, but myself up.

What is sciatica? Is it a neuralgia or a neuritis? Is it of mechanical origin or reflex origin? If a neuralgia, is it due to anemia or is it due to congestion? Or is it due to some constitutional dyscrasia? Often I have seen it due to syphilis, often to malaria, and often of reflex origin. If it is not a neuralgia, is it a neuritis? Is it chronic, acute, or sub-acute? Did the trouble start in the end neuron, peripheral neuron, axis cylinder, or where? According to its cause, so should the treatment be. I have seen it due to a chronic urethritis, of gonorrheal or rheumatic origin, and by removing the local cause you cure the sciatica. I have seen it due to hemorrhoids and rectal ulcer. By

divulsing the sphincter and curing the rectal ulcer with thorough local treatment, you cure the sciatica. I have seen a great many cases of rheumatic origin, with the urine loaded with uric acid, and in such cases you should push your anti-rheumatics until you keep the urine alkaline for 24 to 48 hours.

I have seen cases of sciatica due to malaria, with exacerbations at certain times of the day, with very acute pain, which would disappear only to return again and again. I had that experience in my own case. First I thought it was rheumatic in origin. Then I developed that malarial periodicity.

The question is, what shall the treatment be? Rest—complete rest in bed, even if you have to put on a splint from the sole of the foot to the axilla, just as you would in a fracture. It may be well to flex the limb and put a pillow or a sandbag beneath it, as you would in a fracture. From a medicinal standpoint, hypodermics of morphia and atropia, with complete rest, will cure many of these cases. In some cases I have injected from five to ten drops of sulphuric acid. I had this done in my own case with most beautiful results in the way of freedom from pain.

Again, when we have cases in which there is a neuritis, what is to be done? Fortunately, we can have the nerves stretched. I did this operation in one case where the nerves were bound down by adhesions from a gunshot wound in the thigh, and another from traumatism in the knee. In those cases the nerve-stretching operation was a dernier resort. I used cautery, hot and cold douching, counter-irritation, and actual cautery, and yet I found that all of these things failed, and by nerve-stretching these patients I added years of comfort, happiness and joy to their lives. In one of these patients that I operated on in 1882, the nerves were so drawn that he had to walk in a stooped position. I straightened the limb out and within a year he was able to walk all over his Bluegrass farm.

Andrew Sargeant: I wish to compliment the essayist upon having given us an original paper, but so far as his therapeutics are concerned, I think if he continues to administer treatment as I understood him to delineate it, he will meet with cases in which it will fail him as it has failed others. In dealing with sciatica you must not treat the name; you must treat the condition. It may be a traumatism; it may be a toxemia; it may be a neuritis; it may be a spinal trouble; it may be a peripheral trouble; it may be due to bacterin, and it may be due to toxins. You must find the condition that is responsible for it. The people who are unfriendly to us—the psychopaths and osteopaths, have a remedy called "Spondylotherapy" which has done a great deal of good in these cases. In all these cases we must look for the cause and treat it.

Jno. G. Cecil: I regret that I did not hear all of the paper, as I was called out. Several of the

gentlemen, however, have spoken very wisely in saying that sciatica is of many origins and, if possible, we must discover or uncover the cause and treat it as we would any other similar condition. After all, that is the only rational treatment that we can employ. However, in many cases, we will be unable to discover anything that can be assigned as the cause. I may say that I have never tried the treatment suggested by the essayist. All treatment will fail in certain cases. These cases become notoriously chronic, go from one doctor to another, from the doctor to the half-doctors, and finally get into the hands of all sorts of charlatans and quacks. And, strange to say, they many times get relief. I believe the osteopath has cured many of these cases. While I am not in any sense an advocate of osteopathy, it is undoubtedly true that in many cases massage and muscular movements will break up the adhesions and relieve them. I have once or twice suffered from a mild form of this disease myself. I went to see Dr. Vance and he got out some soldering irons and ran them up and down my spine and on my hips and told me I was cured. When I left there I was much more limber than when I went in, but even that sometimes fails.

In recent years I have been disposed to treat these cases where we cannot assign any definite cause for the trouble, along the lines of elimination, and to that end have generally advised my patients to go to certain water-cure establishments and take sweat-baths, etc. I have more faith in that line of treatment than in any other. Of course, there are a great many things that will relieve these patients temporarily, but many cases are obstinate and recur every time they are subjected to exposure to cold or dampness. I have seen better and more permanent results from sweat baths than from any other line of treatment. If you wish, you can combine with this eliminative treatment; also the so-called curative treatment, iodide, salicylates, etc.

The last case I had was a mean one. This was in a comparatively young man, 35 to 40 years of age. I exhausted every remedy I knew of, most of them with no effect whatever. A masseur with electrical apparatus, treated him for quite a while. Finally I sent him to a water-cure establishment and he made a perfect recovery. For a case in which the cause cannot be diagnosed, that is the treatment I would suggest. Of course, cases of malarial or syphilitic origin should be treated with reference to that particular condition. If you can find a focus, such as Dr. Windell and Dr. Carpenter say they have found, the treatment should be directed accordingly. Remove the cause and the sciatica will take care of itself.

OBSTETRIC ANESTHESIA.

By THOS. K. VANZANDT, Louisville.

A hurried review of the recent American and foreign medical journals at my disposal has impressed me with the fact that the trend of the profession is toward greater care in the selection of anesthetic drugs for certain classes of cases and much more attention to the details of administration. We welcome most heartily this awakening and believe it is high time for the specialist in anesthesia to be accorded his place among the specialists. Since it is our misfortune that the ideal anesthetic has not been discovered, the anesthetic that "abolishes pain by the abolishment of consciousness but without danger to life," it is very gratifying to know that some consideration is to be given the "man behind the gun."

It is conceded that when the physical condition of the patient permits the performance of an operation, it permits of the giving of an anesthetic and in selecting an anesthetic the particular case in hand and the indications to be met must always be considered. This applies to obstetrics as well as general surgery. Normal and operative deliveries are surgical procedures. The indiscriminate, and I may add, careless use of such an active drug as chloroform in obstetrics is to be discouraged. The specialist is needed in this field as surely as he is needed in general surgery, even though we believe the pregnant and parturient woman enjoys a certain immunity.

Arguments have been advanced for and against the free use of anesthetics in obstetrics, but we believe they are justified by both humanitarian and scientific grounds and advocate their employment in all labors.

The selection of the drug to be used is and has long been a favorite subject for debate. The anesthetic must possess the one important requisite upon which the whole of the practice of anesthesia in obstetrics is founded, viz.: to relieve the physical suffering of the patient without interfering with the muscular contractions of the uterus. Of course, in obstetrics, if surgical and not obstetrical anesthesia is indicated, the choice is governed by the same rules that obtain in the absence of the pregnant condition.

The days of narcotic potions and mysterious concoctions to relieve the suffering of a woman in labor have passed and widely advertised hypodermic tablets "for painless labor" will not be discussed. Don't believe nitrous-oxide alone or with oxygen is indicated. Intraspinal anesthesia not practical because of technique necessary and interference with uterine contractions. Chloroform and ether are the two anesthetics that have

given satisfaction. Our consideration will be limited to these two drugs.

By obstetric anesthesia we mean an analgesia, a semi-consciousness, a numbing of the sensibility to pain. This fact must, to some extent, influence us in the choice between chloroform and ether. Which will secure this state with the greater dispatch, with the least inconvenience, with the greater safety to the patient, with the minimum amount of the drug used, and the better end results? The rapidity of action, the question of convenience, and the amount of drug used, are practically of minor importance. Our whole thought should be for the patient's safety at the time and afterwards, the end results.

Clinical experience has proven that ether is unquestionably the safest anesthetic known to-day for prolonged anesthesia.

Hare says: "Ether, when properly administered, will be found to have few contraindications and should be employed in preference to chloroform in every case in which it is possible." Most of the objections to ether are due to faulty administration. Its toxic and dangerous effect is upon the respiratory centers, while it has a stimulating action on the heart. The dominant action of chloroform on tissue is depressing. Its toxic action is chiefly upon the heart through the coronary arteries or through the vasomotor system. The alternate relaxations and contractions of the uterus, the labor pains, have a stimulating effect upon cardiac innervation and help to prevent syncope. The tendency of anesthetics is to produce anaemia of the brain. Labor pains give rise to an engorgement of the brain and the physiological anesthesia attendant upon this cerebral congestion contributes to increase the safety of chloroform as well as to diminish the amount of the drug required. Then, too, we must consider the marked hypertrophy of the left ventricle during pregnancy and the recumbent posture which the woman naturally assumes during delivery. Chloroform is pleasant to take and acts quickly. Ether is unpleasant to take and acts slowly. Chloroform, unlike ether, is not inflammable and can be used better at night without danger from light and fire; most labors occur at night. Vomiting before and after delivery is an objection to ether, but the vomiting after delivery is transient, severe and prolonged vomiting more common when chloroform is used. Both chloroform and ether lower intrauterine pressure in obstetric narcosis. In surgical anesthesia chloroform paralyzes the uterus or lessens the power and frequency of its contractions more than ether. Owing to the fact that the patient recovers quickly from chloroform, it is necessary to administer more of the drug to pro-

long the narcosis while under ether consciousness returns more gradually and it is possible to repair a laceration without more anesthetic. Prolonged administration is not only injurious to mother but is likely to be fatal to the child. Post-partum hemorrhage and uterine atony more frequent with chloroform for the reason that it takes much longer for the uterine ganglia and musculature to recover.

Much attention has lately been called to post-anesthetic poisoning. It may occur after any or all anesthetics. It is believed to be more frequent after chloroform and is often referred to as delayed chloroform poisoning. We have very little knowledge as to its cause and prevention. The condition is an acid intoxication. Fatty degeneration of the liver is a constant feature, probably the direct result of absorption of chloroform or poisons derived from its metabolism from the bowel. The liver is the central organ of metabolism; its cells constantly transform injurious and irritative material into comparatively harmless substances to be eliminated from the system. Pregnancy imposes an extra burden upon the liver, the synthetic function of its cells is interfered with. Every pregnant woman is therefore more or less toxæmic. The cells, failing to perform their function of transformation, are acted upon by these toxic substances and undergo fatty degeneration and necrosis. Chloroform increases these pathological changes more than ether. Most all authorities have insisted that chloroform was the choice in eclampsia. Eclampsia is chiefly an hepatic toxemia. It would seem that ether was the lesser of the two evils and preferable.

The indication for obstetric anesthesia is severity of the pains. The administration should be delayed as long as possible and confined principally to the second stage, the object being to prevent a protracted anesthesia. Chloral or opium much better to hasten the dilatation of a rigid cervix in a prolonged first stage. Partial anesthesia given during the pains, even in the first stage, is frequently very useful. The reflex influence of the pains will often delay the progress of labor in a sensitive, nervous woman who cannot stand pain. This partial anesthesia also helps in cases in which the contractions, while very painful, accomplish very little.

In the second stage the relief from the severity of the pain will many times bring forth voluntary efforts on the part of the patient. In the latter part of the second stage, when maximum distention of the vulva is reached, obstetric anesthesia is not sufficient to abolish pain. The drug should be pushed to the surgical degree for the few moments the head is passing the vaginal outlet. The woman is thus saved a great amount of unnece-

sary pain and the danger of perineal laceration is diminished. In ordinary cases use the anesthetic only during the pains and in quantities only sufficient to dull the pains, complete anesthesia being carefully avoided. Stop administration at completion of second stage (except, of course, when surgical procedures are necessary) for the patient does not appear to enjoy the same immunity after birth of child.

The importance of the psychological factor in obstetrics must not be lost sight of. More suggestion and less anesthetic means fewer forceps deliveries and lacerations.

CONCLUSIONS.

1. Anesthesia during labor diminishes pain and in certain cases aids in the progress of labor.

2. By relaxing the tissues aids cervical dilatation and preservation of the perineum.

3. Prolonged administration certainly tends toward uterine inertia and is not without a deleterious influence upon the child.

4. An anesthetic, if not pushed too far, has no influence on the power, duration, or frequency of the pains.

5. Ether in obstetric practice when pulmonary complications are absent.

6. Uterine atony and post-partum hemorrhage rare following ether anesthesia.

7. Ether should be used in eclampsia.

8. Ether safer than chloroform and danger of post-anesthetic poisoning rare.

9. The use of chloroform in obstetrics will be almost entirely discarded in the near future.

DISCUSSION.

Ben Carlos Frazier: Dr. VanZandt's conclusion as embodied in the last paragraph of his paper is somewhat of a surprise to me. As the discussion proceeds, I would like to know who, among those present, have discarded chloroform for ether in obstetric cases. I have done a fair share of obstetrical work and I think every woman in labor should have chloroform, and I do not believe we can do much harm by beginning it early. As Dr. VanZandt has said, it will sometimes prolong the labor somewhat, but that is about the only harm that can come from the administration of chloroform in labor.

I have seen but one case of eclampsia and I had to handle that alone, except for a negro nurse. Nevertheless, this patient made a good recovery in a comparatively short time.

I have never seen ether used in obstetrical work under any circumstances. I have given the anesthetic in five or six cases in which Cesarean section was done, and a good many times for other men to do forceps delivery. I have also made five or six forceps deliveries giving the anesthetic myself.

I would like to mention a case that I heard of

recently. During the recent Christian Church Convention, there was a doctor here from abroad, a missionary, well known to a good many people here in Kentucky, who, on two different occasions, delivered his wife of a child by Cesarean section, without assistance, using chloroform as the anesthetic.

I do not believe chloroform will ever be discarded for ether in obstetrics.

I have never been able to bring myself to the point of using morphine hyoscin and eactin tablets, hypodermically, in obstetrical work, but I have talked to men who have used them quite a great deal, and they were very much pleased with them.

Bernard J. O'Connor: I was especially interested in the conclusion reached by the essayist in the last paragraph of his paper, that ether will displace chloroform as the anesthetic in obstetrical work. Some four years ago, by force of circumstances, I had to use ether in a case of this kind, and since then I have frequently employed it. As a matter of habit, I often find myself using chloroform, but the effect of ether is equally as good, and possibly better in some cases than chloroform.

Dr. VanZandt mentioned the danger of using chloroform in a room where there is an open fireplace or a lighted gas jet. I do not believe there is much danger from this source unless the ether itself is permitted to come in close proximity to the flame. Ether is not as volatile as benzine or gasoline.

Just one word in regard to the statement that chloroform should not be used in the presence of eclampsia. We must remember that in eclampsia the blood pressure is extremely high, and that the use of ether will, in all probability, increase the blood pressure. For that reason I should think chloroform would be safer in these cases. The etiology of puerperal eclampsia is still unsettled. In many cases it is probably due to a renal toxemia, while in others it is possibly of hepatic origin. Those cases of renal origin would be more irritated by ether than by chloroform, in addition to the influence of the ether on the blood pressure.

Emmet F. Horine: I have certainly enjoyed Dr. VanZandt's paper and he has voiced the sentiments of those engaged in anesthetic work.

In regard to those cases showing albuminuria and certain other symptoms of intoxication during pregnancy, I think the safest anesthetic would be nitrous oxid. Chloroform would certainly be contraindicated on account of its toxic action on the liver and kidneys. Ether could be used but it is not so free from objection as nitrous oxid. We know that following the administration of nitrous oxid, there are never any symptoms of intoxication since nitrous oxid has no effect upon either the heart, liver or kidneys. In obstetric anesthesia, it is only necessary to produce an analgesia, so to speak, and nitrous

oxid will certainly produce this to a sufficient degree. It has been used by quite a number of men, and in those cases showing a nephritic or hepatic condition during pregnancy, nitrous oxid should be used.

Just a word in regard to the use of chloroform in eclampsia. It must be admitted that the blood-pressure is extremely high in eclampsia and the reduction in pressure produced by the chloroform would not be of itself very dangerous. But the factor that should be considered is that chloroform is an exceedingly toxic agent. In eclampsia the liver and kidneys are involved and to administer chloroform in this condition would be to add fuel to the flames. Very likely, in the majority of cases, chloroform will produce an acute atrophy of the liver with fatty degeneration, and in a day or several days the patient will die from acute intoxication. Chloroform produces a central necrosis of the liver macroscopically somewhat similar to phosphorous; although, microscopically, phosphorous attacks the protoplasmic portion of the cells, whereas chloroform affects the nuclear. I think the consensus of opinion is that chloroform should be discarded in eclampsia, and ether, or if possible, nitrous oxid administered.

In uncomplicated cases in which only analgesia is desired, chloroform in minimum amounts might be used, although personally, I consider ether preferable. For the various obstetrical operations and manipulations in which deep anesthesia is necessary, ether should be used. In the toxæmias, nitrous oxid should be first considered and if impossible, ether should be selected. The last conclusion of Dr. VanZandt, that it is only a question of time until chloroform will be discarded in obstetric work, is, I think, absolutely true.

C. H. Harris: I think the proof of the pudding is in the eating thereof. I have delivered probably 700 children, and have used chloroform in labor possibly 500 times, and I have yet to see the first woman die from the effects of chloroform. In labor under ordinary circumstances, we give a little chloroform towards the end of the labor. There is a vast difference between intermittent and continuous anesthesia. When we give good, fresh chloroform in which there is no free chlorine, it does not do any harm. I believe that nitrous oxid gas, under some circumstances, is a good anesthetic, but why not consider the babies? If an adult becomes cyanosed under the administration of nitrous oxid gas, due to depriving the blood of oxygen, why would it not affect the baby the same when administered to the mother. Ether is a good anesthetic when we want complete surgical anesthesia, and there are no contraindications to its administration, but in approximately 700 cases I have my first time to see a woman die from the effects of chloroform anesthesia in labor, and I believe it is a mistake to teach the younger men that

chloroform is dangerous under these circumstances.

Virgil E. Simpson: Just a word in regard to the hyoscin-morphin-cactin tablet which is put out by one of the prominent drug houses of this country. I have never been able to convince myself that this particular combination will accomplish what its manufacturers claim for it; in other words, that the combination of these three agents by that particular house will accomplish any more than if we administer morphin and hyoscin separately in different parts of the body. You may administer a similar amount of morphin in one arm, and a like amount of hyoscin in the other arm, as is contained in these tablets, omitting the cactin, and the results will be equally as satisfactory so far as analgesia is concerned. It has been demonstrated beyond question that cactin is absolutely inert in the quantity contained in these tablets. I have personally taken it and I have used it on the lower animals and have been unable to detect any circulatory influence whatever.

The practice of giving agents to relieve a woman during labor has always appealed to me. If there is any time in the world when a woman has my absolute and unqualified sympathy, it is at the time of childbirth, and I am an advocate of the use of measures which are reasonably safe to tide a woman over this period with as little discomfort as possible. If we are to dispense with chloroform because our ancestors for countless generations have been giving birth to children without chloroform, we had just as well say that it is unwise and unnecessary to advise our patients to remain in bed for a reasonable time after delivery because our aboriginal female ancestors, on the line of march, carrying their agricultural implements, simply squatted down in the leaves when the time arrived, gave birth to a baby and then continued the march. The woman of the 19th century is not constructed after the fashion of her ancestors. Because of the changes brought about by civilization, difference in dress, etc., she is not capable of sustaining the conditions incident to delivery at full term in the same manner as some of her ancestors that we have heard about.

The question of the safety of any anesthetic is dependent upon the degree of concentration in which it is administered. Chloroform is just as safe as ether and *vice versa*, in the respective degrees of concentration necessary to produce a definite degree of anesthesia. The concentration percentage of chloroform necessary to secure that degree of anesthesia is one thing; that of ether is another. Going beyond either of these concentrations is just as dangerous in the one case as in the other. Both affects the nerve cells because of the affinity which the nerve cells have for these agents. Chloroform kills, not because of fatty metamorphosis of the liver, kidney, or

other structures, but as a direct result of vasomotor paralysis. The after-effects of chloroform are far less frequently observed than are those of ether, because the effects of the latter agent are apt to be manifested over a longer period after its administration. If we administer ether in an obstetrical case, we cannot be sure, after twenty-four hours have elapsed, that our patient is going to make a recovery. That is less true of chloroform than ether. Ether is more apt to produce fatty metamorphosis of the liver and other structures than is chloroform. However, it is the degree of concentration that determines the safety of any anesthetic. Properly and judiciously given, the outcome after the administration of either chloroform or ether will be equally satisfactory in practically all cases. It is because of the fact that we have no accurate means of gauging the concentration that disastrous results occur. When we administer such agents as atropin, hyoscin, morphin, or hydrocyanic acid, we know how much to give our patient, and we allow a definite time to elapse between administrations; but in administering an anesthetic at the bedside, oftentimes the doctor himself attending to this as well as to the delivery of the woman, it is absolutely impossible to keep up any definite degree of anesthesia. The patient will lapse into the obstetrical degree of anesthesia at one time, and five minutes later the doctor will discover that his patient is coming out and will push the administration in order to get his patient back under the influence, and she will probably lapse into the surgical degree of anesthesia. There is no regularity about it.

I have been quite fond of using chloral hydrate in certain stages of labor, particularly in primiparae, where I have to deal with a patient that is nervous and apprehensive, where there is evidence of an indisposition on the part of the cervix to relax, and the labor is consequently not making satisfactory progress. In such cases, under the administration of a small dose—say four or five grains—of chloral hydrate, per mouth or per rectum, it is wonderful what a change takes place in four or five hours. The cervix is relaxed and dilated; the patient is less apprehensive, and a great deal of progress has been made.

I am convinced that in the average case, under ordinary circumstances, an anesthetic is indicated in the lying-in room.

Wm. Keller: I agree with Dr. Simpson in a great many of his remarks. I have never given hyoscin or eactin, but I have used morphin on numerous occasions. I have also used chloral hydrate and have obtained just the result that Dr. Simpson outlined. In cases where the pains are severe, and the woman is timid and rather inclined to shirk the pains, I give either chloral hydrate or morphin. The former is preferable, unless morphin is more strongly indicated. You can go away and leave the patient and when you

come back you find that a marvelous change has taken place in your patient.

I wish to condemn the indiscriminate use of chloroform in every case of labor. I believe it is used more frequently than is good for our patients. In selected cases there is nothing with which the physician in the lying-in room can do more good than with chloroform. I have never given ether because I have always found that chloroform served the purpose. One method I have of giving chloroform was taught me by one of the old professors in the college here. When I cannot have an assistant (and in this connection we must take the pocket-book of the patient into consideration), I pour chloroform over the cone and hold it over the face, not long enough to produce surgical anesthesia, but just long enough to take the edge off the pains. When this is done you will find that the patient bears down better and you get better results than under deeper anesthesia. Of course, in cases where we must have complete surgical anesthesia, we must have some one to assist us.

I do not believe I have ever seen a fatal termination from the use of chloroform in the lying-in room. I live in the same neighborhood as Dr. Harris, where there are more babies to the square inch than in any other part of town, and I have had quite a few labor cases in the past twenty years. Chloroform should be given, but only in selected cases. I do not believe I give it on an average of more than one in every ten cases. The reason I do not give it as often now as I did fifteen years ago is because of the after effects on these patients; they get along much better without it.

I have seen very few cases of postpartum hemorrhage. I do not recall but one that followed the administration of chloroform. I believe there is more danger of postpartum hemorrhage where the chloroform is prolonged. I do not think I will ever discard chloroform for ether as long as I can get chloroform, but I wish to repeat that chloroform is given more frequently in obstetrics than is good for our patients.

J. D. Hamilton: I have enjoyed Dr. VanZandt's paper very much. If there is anything that will bring out all the sympathy in a man's soul, it is the suffering of a woman in confinement, and I believe that an anesthetic is indicated in the vast majority of labor cases. I believe too, that the danger in giving chloroform is very much exaggerated. Any agent not properly administered is dangerous. I want to emphasize the statement that I do not believe any man is justified in giving the anesthetic and delivering the woman at the same time; that is two men's work, and both men should be skilled in their work to do full justice to the patient. I recognize the fact that we cannot always have an anesthesiologist to assist us, but I do believe that wherever it is possible we ought to have one.

Dr. VanZandt is right in saying that we have

been careless in our methods of administering the anesthetic. We have not done all that we should for our patients in thus indiscriminately giving chloroform and delivering them.

As to the comparative effects of ether and chloroform in labor, I cannot say, because I have never given ether; chloroform has served me well. I have seen but one woman die as the result of the administration of chloroform in twenty-nine years' practice. I invariably use chloroform. I cannot always have some one with me to administer it, but when I give it to the surgical degree, if I can get some one I am going to have him there. I believe the man who undertakes to give his own anesthetic in all obstetrical cases will sooner or later regret it.

Edward Speidel: The position taken by Dr. VanZandt in regard to the use of ether in preference to chloroform as the anesthetic in obstetrics is indorsed by practically all the recent editions of text-books on obstetrics. However, I think that, in selecting the anesthetic to be used in a given case, experience must also be taken into consideration. Most of these cases are conducted in private homes by the practitioner himself, and the anesthetic with which he is most familiar and can best administer is perhaps the best for him. In all surgical procedures in connection with obstetrical work, the obstetrician should always secure the services of an anesthetist, or some physician to give the anesthetic. Under such circumstances I would leave to the anesthetist the question of the anesthetic to be employed, except that in a case of toxemia of pregnancy, or eclampsia, I would expect him to use ether, as recent researches by men of vast experience in this field have fully demonstrated that the principal pathology in toxemia of pregnancy or eclampsia, is fatty degeneration of the liver and, as it is contended that chloroform tends to produce this very condition, I prefer to follow the advice of men of such broad experience. Therefore, as stated, I would expect the anesthetist, under such circumstances, to use ether.

I heartily indorse what Dr. Simpson and Dr. Hamilton have said in regard to making labor as easily as possible. In the multipara the process of labor is comparatively short, and where the parts have been properly dilated the pains need not be so severe. However, in the primipara, who must go through a painful stage of from 16 to 24 hours, we should do everything possible, consistent with safety, to alleviate her suffering. I often wonder how the average man would conduct himself under similar circumstances. Therefore, in a prolonged first stage of labor, where dilatation is slow, I see no objection to the use of an anesthetic.

I have used the H. M. C. tablet, and I have used morphin straight and in connection with atropin. One objection to the use of the H. M. C. tablet is that it flushes the countenance, and

in some cases the patient becomes hysterical and frightens the family. However, it gives her more rest, allays her nervousness, and astonishes every one who use it to find how rapidly dilatation in the first stage of labor proceeds under the influence of the anesthetic.

Care should be exercised in the use of morphin. It should be given in the first stage of labor only. If used in the second stage the patient is apt to have a narcotized infant. Consequently, after full dilatation has been secured, and the bag of waters has ruptured, I think that morphin and other narcotics are contraindicated, because they will undoubtedly affect the child.

The degree of anesthesia during the second stage of labor should be in accordance with the pains, and even where the obstetrician gives the anesthetic himself he can regulate the amount administered. I am in the habit of giving the anesthetic myself and conducting the labor with one hand which is kept aseptic. I simply pour chloroform on the mask and place it over the face. Then, judging the amount of pain with the other hand, I either lift it or depress it upon the face. In this way I give the patient either the smell of chloroform or the actual effect as desired. This can be kept up for an hour without doing any harm, and the labor conducted very efficiently. If it is found that the patient is not bearing down properly, lifting the mask will accomplish the desired result.

When the head crosses the vulva and is about to come out, the patient should be surgically anesthetized, and delivery should be delayed in order that the head may be pulled out between pains. That can only be done with the patient under absolute control by producing a surgical degree of anesthesia for a few moments.

In my opinion, forceps operations, or any other procedures of that nature, cannot be safely conducted without the assistance of an anesthetist. True, we do not hear of many deaths from this cause, but if any practitioner would be unfortunate enough to have a death while attempting to carry out such a procedure alone, he would be in a bad fix, because it could be readily proven that he should have had some one to assist him. Where the obstetrician gives the anesthetic himself, not only is he unable to be aseptic in his work, but he must be hasty in his forceps delivery, and there is greater liability of lacerating the perineum and other accidents.

I have not seen any great preponderance of uterine inertia and postpartum hemorrhage in labor cases in which an anesthetic had been given. In versions and other operations of that character, I always secure complete surgical anesthesia, the anesthetic being administered by a reliable assistant, before proceeding to do the work. Furthermore, in work of that kind, I always supplement it by uterine douching and pack gauze into the uterus.

While the prediction of the essayist that

chloroform will be discarded for ether may be true, I believe it will be a long time before this comes to pass.

T. K. VanZandt, (Closing): I am certainly gratified and complimented by this generous discussion. The subject has been so thoroughly gone over that there is nothing left to be said.

The point touched upon by Dr. Harris was one of the main reasons for the presentation of this paper; that is, I wanted to teach the younger men to avoid the use of chloroform. We have learned that the after effects of this anesthetic, be it given to the degree of analgesia or complete anesthesia, are much more harmful than we formerly believed. Another reason why I wrote this paper was to present a plea for the employment of a specialist in all work requiring anesthesia. As stated in the last paragraph of my paper, I think the day is coming when ether will be the anesthetic to the exclusion of chloroform, not only in obstetrics, but in all surgical work.

So many good points have been brought out in the discussion that I will not attempt to go over them all. The arguments advanced by one side have been answered by those presented by the other side, and to take up all of them would keep you here too long. I wish to thank you again for the generous discussion you have accorded this paper.

SOME PERSONAL EXPERIENCES WITH VANCOTT'S VACCINE.*

By B. J. O'CONNOR, Louisville.

In the July, 1911, number of the *New York State Journal of Medicine* Dr. J. W. VanCott narrates his observations on a series of 75 cases of infection, which were treated by injections of a combined bacterial vaccine of the following composition:

Streptococci, 50 million; staphylococci, 500 million; colon bacilli, 200 million.

The vaccine was prepared for him, by a well-known manufacturing drug firm, according to the commonly accepted method of preparation for stock vaccines. His cases embraced puerperal sepsis, erysipelas, abscesses, phlegmons, lymphangitis, salpingitis and miscellaneous pyogenic infections, of varying degrees of severity. He concludes as a result of his study that a combined vaccine of this nature is of considerable therapeutic value. As various features connected with the use of this vaccine appear in my cases I shall refrain from quoting his paper at greater length.

There is a slight but not unimportant alteration in the above formula as this product is marketed, to-day, by this same firm. The number of streptococci to each c.c. has been

reduced to 25 million, and there has been added thereto 25 millions of the diplococci pneumoniae. At whose suggestion or when this change was made I am unable to say, but the latter represents the present formula. The change widens the utility and applicability of the vaccine.

In the *Journal of the A. M. A.*, of November 25th, 1911, Polak in a splendid article on the treatment of pelvic infections details about 150 cases of thrombophlebitis, salpingitis, appendicitis, pyelitis, pelvic cellulitis and like infectious processes, which he treated with the VanCott vaccine in conjunction with other standard modes of treatment. As a result of his observations he recommends the frequent and early use of this vaccine.

My personal experiences with the mixed vaccine, suggested by VanCott, have occurred during the past twelve months. About a year ago a patient with a typical pernicious anaemia, who had been under my care for several years, suffered an acute exacerbation of the disease. Despite several months rest in bed and excellent nursing, combined with the administration of sodium cacodylate and iron citrate hypodermatically, and the liberal use of intestinal antiseptics she continued to steadily lose strength. Her temperature during this time ranged from 96 to 99 on some days to 99 to 104 on others; the anaemia, and symptoms dependent thereon, becoming daily more marked. On the basis that the disease was probably due to some obscure intestinal infection we decided to utilize the mixed vaccine of VanCott in the hope of stimulating the resistive powers so that the temperature and infection might be controlled. Three doses of the vaccine were given at intervals of about four days. Beyond a slight local reaction no effects could be noted on the temperature or any of the symptoms. Its use was discontinued and about one week later she sank into a coma which lasted almost 72 hours before her demise. This patient's vital powers were at such a low ebb before the vaccine was utilized that it was given only as a dernier effort. To illustrate forcibly her de-vitalized condition during the period of this medication, there occurred an indolent inflammation at the site of the last injection of iron citrate which shortly before her death terminated in a focalized gangrene and a slough.

I have had four cases of appendicitis which were given the VanCott vaccine. Two of these were of the perforative type with peritonitis which were subjected to operation. In these cases the vaccine was used on account of complications. The third patient, an elderly man with a tissue paper abdominal wall, who presented in addition to the typical symptoms of a recurrent attack, a palpable enlargement at the head of the colon about

*Read before the Kentucky State Medical Association, Louisville, Tuesday, October 29, 1912.

the size of a barlow knife. The pulse rate was low and the temperature at no time exceeded 100. On account of his age, infirmity and the subacute nature of the attack we gave him three injections of the mixed vaccine at intervals of three days in conjunction with other treatment. Within 24 hours after the first injection there was such a notable improvement in all the manifestations that I felt certain that he was almost beyond any danger. Two days after the third injection the tenderness and tumor mas had almost entirely disappeared. I feel reasonably certain that the vaccine shortened the course of the disease. He still has his appendix, however, and although he has worked steadily for the past four months he has experienced several attacks of indigestion (?) following dietetic indiscretions.

The last patient with appendicitis on whom I used the VanCott has just returned home from the infirmary minus his appendix. His attack, was an initial one which started out very mildly. I saw him a few hours after the onset, cleansed out the lower bowel and restricted everything by mouth. Six hours later I gave 1 c.c. of VanCott's mixture as his temperature had increased from normal to 100.2. The abdominal pain was more decided shortly after the injection and he was given a 1-8th of morphine hypodermatically. The next morning the pain made him so restless that a 1-4th grain of morphine was administered. His temperature was still 100 and pulse 88. In the afternoon the pain was again severe and his temperature had increased to 102 and the pulse to 108. An operation was advised and after consultation agreed upon. The appendix, which was removed the same evening showed a gangrene of the mucosa and muscularis with a beginning gangrene of the peritoneal layer. Owing to an apparent extension of the gangrene extending to the head of the colon the stump could not be perfectly closed, the omentum was brought down to wall off the area and free tubal and gauze drainage was allowed. A few hours after operation his temperature was normal and remained so throughout his convalescence which was unusually smooth. The amount of drainage was apparently less than usual for cases of this nature. There may be some question as to whether the vaccine proved to be of any benefit to this patient. That it had anything to do with the gangrene of the appendix seems unreasonable.

In my first patient with perforative appendicitis on whom the vaccine was used the removal of the appendix was delayed on account of a multiplicity of medical attendants until almost 18 hours after the perforation. The peritoneal cavity contained almost a pint of pus, the intestines in the neighborhood of

the appendix were covered with sero-purulent exudate and all the abdominal viscera showed distinct evidences of a general peritonitis. After the operation the patient felt considerable relief but his condition was anything but favorable. On the fourth day a painful swelling developed in the right parotid, resembling an ordinary attack of mumps. Several days later fluctuation could be detected and the skin became reddened. The gland was incised and drained. At this time another metastatic abscess commenced to form in the left buttock. The drainage from the abdominal wound which was markedly inflamed, was quite profuse and of a distinct purulent character. The first dose of the VanCott not only seemed to reduce the temperature but also exerted a beneficial effect at the foci of infection. The abscess in the buttock was opened. Three doses of the vaccine were given subsequently at intervals of three days. The drainage materially lessened after each injection, the temperature completely disappeared and the incisions soon assumed a healthy and healing appearance. The abdominal wound which had gaped widely apart owing to the sutures pulling through the inflamed tissue was resutured under cocaine anesthesia. The patient left the infirmary five weeks from the date of entry and after a few weeks' convalescence in the country returned to his work. Proctoclysis, the Fowler position and special nursing probably deserve as much credit for the patient's recovery as the vaccines.

In the second case of perforative appendicitis the patient came under my attention within an hour of his perforation. His temperature was still normal, his pulse 72 but his abdomen showed universal rigidity and his expression typified the most exquisite pain. The appendiceal pain was first noted some six hours previously but only became unbearable a short time before I was called. About a year previous to this attack I had seen him through a mild attack. On this occasion, however, his mother had completely filled him with castor oil and salts and the appendix had apparently yielded to the pressure. After making the diagnosis I told him that I could not give him anything to ease his pain until he gave his consent for an immediate operation. The pain was such that he readily consented and he was on the table an hour afterwards. The abdomen contained several pints of thin watery feces, exuding in a stream from a small perforation at the base of the appendix. The appendix was removed, the stump carefully sutured, liberal drainage was provided through the wound and by means of a flank incision. For several days he did splendidly, then an attack of pleurisy was ushered in by chill, high fever, a rapid

pulse and pain. Within 12 hours an extensive exudate, apparently of a fibrinous nature, caused an almost complete dullness of the left anterior chest wall. His chest was strapped with adhesive and a dose of VanCott's administered. There was a distinct improvement within 24 hours, his temperature fell to 98 and at no time subsequently passed 100. A second injection on the fourth day seemed to bring about a considerable diminution in the area of dullness and a few days after the third injection the dullness had completely disappeared. This patient left the hospital within three weeks apparently in better shape than prior to his illness.

Two cases of fibrinous pleurisy in young people with characteristics almost identical to the preceding have been given the same treatment with equally striking results. One patient treated at home cleared up within ten days. The second patient whose temperature was higher became delirious and unmanageable at home. He was removed to the infirmary. The first dose of the VanCott seemed to increase his temperature and delirium for a few hours, he then had a heavy sweat and commenced to improve, after the second injection his temperature fell to normal and the exudate almost completely disappeared. He received two more injections before he left the infirmary.

Another patient with a sero-fibrinous pleurisy from whom I twice removed about a pint and a half of fluid, which was loaded with pneumococci was also given several injections of the VanCott. He was running a temperature up to 102.5 prior to the injections and aspirations but since then the temperature has remained normal, his appetite and general condition has improved. Unfortunately he was not willing for me to continue the injections. The use of the two doses in his case did not seem to exert any effect towards the absorption of the fluid. Whether the cessation of his fever was due entirely to the aspiration I am unable to say.

Several cases of urinary infections have also been treated with apparently beneficial results. The first was a man of 80 years who had been subjected to a perineal prostatectomy on account of complete retention. Owing to the efforts to give him instrumental relief for more than a week preceding the operation we fully anticipated trouble after the operation. It came rather promptly in the form of chills and high fever, about the third day after the operation. The vaccine was started at the onset of the septic condition. A slight local and general reaction was noted followed in some 12 hours by a distinct amelioration of the threatening symptoms. After two more doses at three day intervals he seemed to be well beyond danger and made a

perfect recovery. The Murphy drip, frequent irrigation of the bladder, free drainage and good nursing no doubt contributed largely to his recovery. He left the infirmary three weeks after the operation with a comparatively small urinary fistula. Four more injections of the VanCott after his return home failed to close the fistula and an autogenous vaccine was prepared. After he had received three doses of the autogenous vaccine the fistula closed and the pyuria and bacteriuria disappeared.

The second case of urinary infection treated with injections of VanCott's vaccine, was that of a clergyman, 50 years of age, who after several attacks of ureteral colic, voided the fragments of an apparently recently formed calculus. These fragments were imbedded in small blood clots of which the patient voided quite a number. After the first fragments passed a considerable quantity of urine which had evidently been retained in the pelvis of the kidney for several days was voided. A colon bacillus infection with a moderate pyuria and mild general symptoms followed. Four injections of the VanCott were administered with a distinct improvement in the condition of the urine. The pyuria entirely disappeared and only a slight mucous flocculency with a few bacteria could be found microscopically. Ten days later the urine was perfectly normal. Urotropin and piperazine were also administered in conjunction with the vaccine.

I have also treated three cases of postpartum infection with the VanCott combination. The first patient had a large pelvic abscess, following an abortion, when she came under my attention. The abscess was opened and drained through the Cul-de-sac. A distinct amelioration of the symptoms was naturally the result. This woman was so emaciated and devitalized as a result of her long continued disease, that I deemed it advisable to give her several injections of the VanCott to fortify her resistance and hasten her recovery. After each injection, four in all being given, a slight increase in the amount of discharge was noticeable for a few hours and then a considerable decrease in the amount would follow. At the end of two weeks the fistula had closed and at the end of a month the patient felt better than before her illness. This patient would probably have fully recovered without the vaccine but scarcely in such a short time. The suppurative process was of such long standing when I first saw her that I felt certain that amyloid degeneration of the tissues was sufficiently advanced to make the outcome disastrous.

The other cases of postpartum infection were seen in consultation. The first case was one in which a severe infection followed an

intrauterine douche. The patient was delirious, with a temperature of 105, and showed extreme tenderness of the uterus and pelvic organs. The cervix, which had been badly lacerated, was covered with a sero-fibrinous exudate, the lochial discharge, which was scant, was more purulent than sanguineous. The uterus was patulent and contained no clots. The cervix and the body of the uterus was carefully swabbed with tincture of iodine. One half c.c. of the VanCott was given immediately and the attending physician advised to give another half the next morning if no improvement was observable. Much to the surprise of the attending physician he found his patient practically normal the next day. The temperature on that afternoon rose to 100 and was still above normal on the following day but after a second dose of the vaccine the fever entirely disappeared, and the patient made a prompt recovery. In the other case of postpartum infection a subacute infection followed in the wake of a difficult labor. A persistent occipital had required the use of forceps. There was a slight perineal laceration, which was immediately repaired. Two days later a chilliness ushered in a temperature of 102.5. The vagina, cervix, uterus and perineum were carefully examined and showed no distinct evidence of any infection. Pressure on the body of the uterus elicited only a moderate amount of tenderness. A dose of the VanCott was administered, it was followed for a few hours by a slight accentuation of the general symptoms, and then by a rapid improvement. After two more doses at intervals of 72 hours every symptom of the infection had disappeared.

My object in reporting these cases is to call the attention of the profession to what I believe to be a valuable adjunct to our therapeutic resources in combatting, during the acute stages, various septic and pyogenic infections. The combined vaccines do not meet with the universal approval of expert vaccine technicians, being held by many in the same class as a shot-gun prescription. But when we consider the many difficulties to the average practitioner of an accurate bacteriologic diagnosis in the many pyogenic infections that he encounters and the fact that the VanCott vaccine contains in suitable dosage, ready for immediate administration, all of the more common pyogenic bacteria, plus the observations of VanCott, Pollak and many others that good results follow the use of such a combination, I feel that the clinical observations, should carry more weight than the laboratory theories.

As with all other vaccines, this combination should be considered solely as an adjunct to the universally accepted modes of

management for infectious conditions due to the pyogenic bacteria, no matter whether those methods be surgical, medicinal or mechanical.

The acute infections, rather than the chronic, subacute or indolent types of infection constitute in my opinion the special field in which the combined vaccines are indicated. Although it is slightly more difficult in such character of cases to draw accurate deductions as to the exact amount of good which follows the use of any therapeutic agent, I believe that almost everyone, who has employed the VanCott vaccine any way extensively, will agree with me, in the following conclusions: First that the vaccine seldom, if ever, has caused any apparent harm to the patient. Secondly, that in many cases in which we are somewhat fearful of the ultimate outcome, that one or two injections of the vaccine will bring about conditions which promptly dispell any apprehensions of great danger. Thirdly that the gravity of many of these infections is decidedly less when the vaccine is used early. (My personal opinion, based upon a good many cases in which I have employed vaccines, leads me to believe that the early administration of vaccines is almost as important as the early use of antitoxic or antilytic sera.) Lastly, that in cases in which we employ vaccines scientifically we do not meet with complications, extensions or long drawn out illnesses and questionable convalescences, that were not unrarely seen with older methods of treatment.

DISCUSSION.

Edward B. Richey: I appreciate the report made by Dr. O'Connor to-night, because of the fact that I have frequently used VanCott's vaccine, and I wish to emphasize his statement that it should be used early. I believe that, when a positive diagnosis has been made, the earlier it is given the better results we will get. I also agree with him that it is often a valuable adjunct to other forms of treatment. I have used it in more than 200 cases with satisfactory results in 75 per cent of them.

J. Garland Sherrill: Properly administered in selected cases, VanCott's vaccine is probably of some benefit. I feel, however, that when it comes to treating acute infectious conditions, such as appendicitis for example, with vaccine, it is like shooting at a bear with a pop-gun. The patient will fare a great deal better if we operate promptly. During the past ten years the work of the majority of surgeons in handling appendicitis has improved to such a degree that we now see comparatively few of the late complications mentioned by Dr. O'Connor, and in which he used VanCott's vaccine. It has been my impression that the results from the use of this vaccine have been much better in chronic pyo-

genic processes than in acute conditions. In acute processes the infection is so rapid that before the vaccine has had time to produce an effect, the tissue destruction has progressed to such an extent that it can do no good.

Arch Dixon, (Henderson): I agree with one of the speakers that we should not delay operation in appendicitis, but I also agree with Dr. O'Connor that where we have a perforated appendix, with general peritonitis, if the appendix be removed in time, the vaccines will do a wonderful lot of good. I recall one case especially in a patient that I believe would have died in less than twelve hours without the use of vaccine.

I have been called in consultation in several cases of puerperal infection in which I have advised the use of vaccine with marked results.

In country towns where a bacteriologist is not available, and a vaccine prepared from the bacilli that are causing the infection cannot be had, it is my plan to use a polyvalent stock vaccine. Call it a "shot-gun" vaccine if you will, but it does the work; if one type of bacteria does not hit the mark, another will. In a great many of these cases we find, not only the streptococcus but the staphylococcus and the bacillus coli communis, and I believe that with a more general use of vaccines we will get better results in these cases than we are getting now. A great many doctors in my section of the country are afraid to use the vaccines. They are afraid of the possibility of an anaphylaxis, such as we occasionally see following the use of the diphtheria antitoxin. However, I have been using them for a year or more with very good results.

In acute cases we cannot wait the length of time necessary to secure an autogenous vaccine, and we are obliged to use the stock vaccines, and I believe that the latter are just as good except in some particular cases. I know that I have had good results from them.

I agree with Dr. Sherrill that the thing to do in appendicitis is to operate as soon as we make the diagnosis.

Arthur T. McCormack, (Bowling Green): As a practical suggestion, I would like to mention the fact that the State Board of Health, through its bacteriological laboratory, is now able to furnish Mulford's vaccines and other bacteriological products at a discount of 40 per cent. from list prices for the benefit of indigent persons who are unable to pay the full price.

My experience with the VanCott formula has been limited to the last six or eight months. I was particularly interested in a case of angioneurosis, diagnosed by Dr. Billings, of Chicago, as of malarial origin. Active treatment for chronic malaria apparently relieved her for a time, but there was a recurrence of the symptoms with some indications of an obscure intestinal infection, and at the suggestion of Dr. Simpson I used the VanCott formula with very good results. She was relieved by the first injection, and

after the second the swelling and pain entirely disappeared.

Probably the most delightful result I have obtained from the use of any bacterial vaccine has been from the colon vaccine in cases of chronic infection of the gallbladder, apparently without stones, as evidenced by the absence of the characteristic attacks of gallstone colic. I first used it in a case following operation, in which there was a discharge of a large amount of the black, tarry, peculiar-smelling material that we see in cases where no stones are present. Following this I used it in a series of eight cases, in which operation was not done, with extremely gratifying results.

Chas. W. Hibbitt: Did those cases have fever?

A. T. McCormack: No, sir. They were chronic cases. I think in some of them the temperature went as high as 99 degrees F., but the rapidity of the pulse was entirely out of proportion to the temperature. They had the color, and the tenderness over the gallbladder, without having had any attacks of gallstone colic.

Bernard J. O'Connor, (Closing): I wish to thank the gentlemen for their discussion.

I would say to the surgeons that no one is more ready to recognize surgical indications and to meet them by advising operation than I am. However, in every case of appendicitis, operation is not wise. Many cases of catarrhal appendicitis recover without operation. Again, not every patient is willing to undergo operation. Where we can obtain the patient's consent, and have operation done in the first few hours, I recommend that procedure, because I think the chances are more favorable at that time.

Another point that has been brought out is in regard to the use of vaccines in chronic rather than acute infections. Any one who is acquainted with the recent literature on vaccine therapy is fully informed of the fact that vaccines are now being used in acute conditions about as frequently as in chronic conditions. As stated in the report, it is a hard matter to determine the benefit derived from the use of vaccines in infections that run a comparatively short course, and if neglected they become chronic and refractory to all forms of treatment.

The fact that vaccine therapy is being derided and made light of by the public press is to my mind deplorable. Any one who has faith in diphtheria anti-toxin must necessarily believe in vaccine therapy, because the principles are the same. I do believe, however, that vaccines, under certain circumstances, are potent for a great deal of harm. One of our local physicians almost induced an attack of pneumonia in himself by using staphylococic vaccine once a day. After a week's rest and then taking a dose once a week, his bronchitis promptly cleared up.

I have used vaccine in one case of cystitis. The urine from the bladder was cultured and an autogenous vaccine made. The injection of the

vaccine probably lit up an old gallbladder trouble and the patient died forty-eight hours after the first injection.

It is necessary to be more careful in the use of autogenous vaccines than with the stock vaccines. We should commence with a smaller dose of the former. The dose is not always carefully estimated, and the possibility for harm is greater with the autogenous than with the stock vaccines.

NEPHRECTOMY.

(REPORT OF CASE AND SPECIMEN.)

By J. HUNTER PEAK, Louisville.

During the month of May, 1912, I was called, in consultation with Dr. Melton, to see a woman, 45 years of age, who has given birth to eleven children, seven of whom are living. She dated her suffering from the birth of her second child, 25 years ago. Upon examination I found a tumor occupying almost the entire right side of the abdomen, from the ribs down to near the pelvis. Upon palpitation it was very easy to determine that it was a kidney condition, and the symptoms of which she complained also pointed to such a condition. Her trouble became very much worse in January last, which she thinks was due to a fall. From that time until May she suffered at intervals very greatly. Sometimes the tumor mass would be much larger than at other times, and it would become smaller after she had voided considerable urine.

Analysis of a catheterized specimen of urine from the left ureter, at the time I first saw her, was normal, but the urine from the bladder showed a great many pus cells and pus.

This patient was removed to the Infirmary on May 21st, and operated upon. This specimen is a part of the mass removed. It might be described as the shell of the cortex of the kidney with the sac. It was sacculated, even the ureter being sacculated to a large extent. The pelvis of the kidney was large enough to hold three painful of fluid, which upon examination was found to contain staphylococci and colon bacilli. There was no evidence of a tubercular condition at the time of operation; no stone was found, and there was no apparent cause for the obstruction of the ureter.

The operation was rendered somewhat difficult by adhesions at the upper part of the kidney, and very troublesome hemorrhage occurred during the enucleation. The mass was adherent to nearly all the structures in the immediate neighborhood, but the enucleation was easy except at the upper pole, where it was very difficult with considerable venous

hemorrhage which was controlled by hot packs. I was able to remove the mass transperitoneally making an incision at the outer border of the rectus, beginning at the border of the ribs and extending eight or ten inches down. However, it was found that the growth was too large to be removed through this opening. With a trocar canula I evacuated the fluid and closed the opening with a suture, after which it was comparatively easy to accomplish its removal. A pair of Pruit forceps was placed on each side, with the points coming together, and the mass removed on the distal side. Then I ligated the veins and arteries and cut off as much of the ureter as I could, leaving the stump open. I did not search for a stone because the patient was in very bad shape on account of hemorrhage and shock. At the time of operation and for two weeks prior, her temperature had ranged from 102 to 104. When she went on the table it was 103 1-2; pulse 130.

After putting her to bed she was given saline per rectum, and other stimulants, in order to keep the other kidney functioning. She rallied nicely and in two or three days was seemingly in fine shape. I neglected to say that the anterior wound was sutured without drainage, and the stab wound made over the crest of the ileum, far back, for the purpose of drainage. This continued to drain for about two weeks after she went home. She was in the hospital about two weeks, going home on the 15th day following the operation. At the end of about the fourth week, the wound closed and she has been perfectly well ever since.

I have brought this patient here to-night and I would be glad to have you examine her if you desire to do so.

DISCUSSION.

W. C. Dugan: I differ with Dr. Peak in regard to dealing with a condition of this kind. I do not believe that, with a patient running a temperature of 102 to 104, profoundly septic, should be subjected to a primary nephrectomy. I would like to ask Dr. Peak to say why he did a nephrectomy as a primary rather than a secondary operation in this case. I am rather surprised that the doctor succeeded in getting his patient off the table. He is certainly to be congratulated.

I think the safest way to deal with a case such as this is to first do a nephrotomy, going in from behind, establishing drainage, and eliminating the factor of sepsis; then at a later date, do a nephrectomy.

J. Hunter Peak, (Closing): In answer to Dr. Dugan's question, I will say that this woman had suffered so long from this condition that I believed she had developed a certain degree of immunity, notwithstanding the high temperature.

She would suffer for twenty-four to thirty-six hours, and under the administration of morphia, and after she had passed a considerable quantity of this material, she would get relief and get up and go about for a week or a month, and then have the same thing over again. At the time I saw her, she had been suffering a great deal of pain almost continuously for two weeks, and during that time the urine had been relatively clear. Believing that her condition was not as serious as her temperature seemed to indicate, I considered it advisable to remove the kidney at once. Any one who has ever removed a kidney as a secondary operation following drainage knows what it means in the way of adhesions, making its removal very difficult, while primary removal of the kidney, especially transperitonically, is comparatively easy. I am satisfied that this kidney could not have been removed satisfactorily in any other way; first, because the adhesions would have made it impossible to remove in any other way; and, second, I believe we are able to control the hemorrhage much better in this way.

So far as the results are concerned, I think they speak for themselves. The patient is here, in perfect health, and she has been ever since she went home. If the obstruction in this case was produced by a stone, it is still there because it has never passed.

MEDICAL PROGRESS

DEPARTMENT OF MENTAL AND NERVOUS DISEASES.

By MILTON BOARD, Louisville.

IS ALCOHOL A HEART STIMULANT?

Under this title Dr. John M. Shaller, of Denver, Col., presents some very interesting thoughts in the Spring number, 1912 of the *Journal of Inebriety*. He classes alcohol with nitro-glycerine, opium and atropine, claiming that, they act through the vaso-dilator nerves upon the involuntary muscle fibers of the small arteries.

He answers the question in the affirmative by stating that if by stimulation we mean relaxing the arterioles thereby flushing the capillaries of the skin, brain and skeletal muscles. The question of what is stimulation becomes a very important one, worthy of our deepest thought and most thorough investigation. Dr. Shaller compares the action of the foregoing drugs with digitalis, which he asserts is the truest heart tonic and stimulant, in that it contracts the arterioles by toning their involuntary muscle fibers and acts similarly upon the cardiac.

It causes muscular activity, produces strength of action and actually increases the size of the muscle fiber through digitalis ex-

ercise; the heart beats slower with more vigor and the blood pressure is increased. This is true cardiac stimulation, which unfortunately cannot be quickly produced, hence digitalis is of no value in an emergency. Cardiac stimulation is the increase of the force of systolic action as well as the blood pressure; increase in blood pressure can be produced only by contracting the arterioles not by dilating them, by this standard then, alcohol is not a heart stimulant. Taking up the effects of alcohol on the circulation the writer states that the arterioles are relaxed through paralysis of the vaso-constrictor nerve. In fact contracted muscle fibers are relieved of their enforced tension by alcohol. This permits the blood to flow into the surface capillaries and unload the crowded vein, in which the blood has been accumulating during the emergency.

In internal congestions this filling up of the internal veins is the cause of paleness. The veins are the only reservoirs which have the capacity to hold the blood forced out of the smaller arteries by muscular contraction. To relieve the over-filled veins and return the blood to the cutaneous and muscle capillaries is a very important matter, not only to relieve pain, but sometimes to save life. This action of alcohol, of nitroglycerine, opium or atropine is not stimulation, it is relaxation, or perhaps better dilatation. The warm blood refills the capillaries of the skin, brain and skeletal muscles; there is a pleasant sensation of increased heat and relief of pain. The writer describes the well known physiological effects of alcohol and concludes as follows:

"It is impossible to give even the smallest physiological dose of alcohol without obtaining its narcotic effects."

"Alcohol is a narcotic which cannot produce its so-called stimulating effect independently of its narcotic one. They are identical."

"The effects produced by a social glass are not stimulating, but narcotic. If we will but take the pains to compare the effects of alcohol with those of opium, we will find they are similar."

"The rapidity with which narcotic effects are produced is probably a matter of more or less personal experience with each of us. As soon as the flushing of the face is felt accompanied with fullness of the head and the sense of general wellbeing just so rapidly are the narcotic effects of alcohol produced."

"The so-called cerebral excitement shown by increased liveliness of manner or of speech follows the above primary effects. The narcotic effects are the first to be produced probably the only one; without them relief in all acute conditions accompanied by

coldness and paleness of the surface could not follow their administration."

"Alcohol is a powerful inhibitor of the higher nerve centers."

"It would be impossible for many men to act foolishly, immodestly or criminally unless the higher centers were paralyzed, which permits lower traits to come to the surface. Stimulants cannot produce such effects as narcotics do. The so-called period of stimulation is one of exhilaration, of delirium caused by narcotism."

"This is plain when marked conditions are present."

"We should be careful not to confuse mental excitement with narcotism or with the delirium of disease or with cardiac stimulation."

THE WASSERMANN REACTION AND ALCOHOL.

In the August 5th, number of *The Journal of the American Medical Association*, Doctors Craig and Nichols raise a very important point. The Wassermann test though it has been found to occur in a few other diseases, has come to be pretty generally accepted as a practical test for syphilis. They raise the question, however, of its value in a user of alcohol even when taken in moderation; and as the majority of syphilitics drink more or less, the practical use of the test is in danger of being seriously embarrassed. They suggest the complete withdrawal of alcohol for two or three days before the test is made. This can usually only be accomplished with certainty in a hospital where restrictions are thrown around patients.

STRYCHNINE NOT A SAFE MEDICINE.

In the spring number, 1912, of the *Journal of Inebriety* this subject is treated briefly, the Editor calling attention to the fact that persons given continuous doses of strychnine, the basis of so-called gold cures for alcoholism have suffered from paralysis particularly of the motor nerves. Withdrawal of the strychnine caused the paralysis to disappear. Study of the effect of the drug on inebriates shows that a number are hyper-sensitive to its effects, one or two doses of one-sixtieth of a grain will sometimes be followed by a spasmodic action and muscular tension that is very dangerous. When small doses are given for a long period an unexplained sort of dementia occurs. The patient becomes indifferent to the surroundings, to exercise both physical and mental, and is precipitated into what resembles extreme old age. The muscles lose their elasticity and become hard. The patient walks with hesitation and all the acts of the patient are performed as if unconscious of their import. A species of progressive muscular atrophy seems to follow,

which improves when the drug is withdrawn. Experience shows that it is a safe drug in only a limited number of cases and then in very small doses given for a few weeks discontinued and taken up again after a long interval. It is generally contraindicated in all forms of hemiplegia. In the toxemias and congestions from alcohol and inebriety, it should be used with great caution and careful examination of its effects; otherwise much danger will follow.

WATER AS A CURATIVE AGENT IN THE TREATMENT OF INEBRIETY.

In the same issue of the *Journal of Inebriety* it is stated that a Paris doctor has announced in great detail a method of cure of inebriety which is at least suggestive and far more rational than the various drug combinations that have been urged.

The inebriate is given colored water in four ounce doses every two hours. The water is first mixed with wine in very small quantities. Then the wine is withdrawn and phosphoric acid substituted so that the patient practically gets two or three drops with each dose of water. The patient is told that he can drink his usual quantity of spirits, but he is required to take his colored water as medicine, the nature of which is unknown to him. After two or three days he loses his taste for spirits, becomes greatly disgusted with them, says they are harmful and will not use them any more. The results after two weeks of treatment is full restoration and a degree of vigor which is very evident. The water is reduced in quantity until one ounce is taken every two hours and this is kept up for a number of weeks, the patient realizing that he is unable to drink with pleasure and feeling no desire or taste for it. This is a new application of an old remedy which is deserving of much attention. Suggestion forming a large part of the various so-called cures for alcoholism the use of as harmless a remedy as water is preferable to strychnine and emetics.

INSANITY IN LITERARY GENIUS.

Dr. Eva Charlotte Reid, Assistant Physician of the Government Hospital for the Insane, Washington, D. C., has written a very interesting thesis which appears in the April number of the *American Journal of Insanity*. Numerous illustrations are given of historic characters who suffered from insanity of the manic-depressive type.

"The theory that genius is allied to insanity has found many advocates, it has on the other hand many opponents. There is a strong sentimental reason for objecting to the association of that which is most noble and sublime in the mind of man with that state

which is considered the saddest, most pathetic and even disgraceful. Joly states that: "It is not necessary to refuse the theory of genius and insanity, for strength is not weakness, health is not disease; and for the rest the cases quoted in favor of these hypotheses are only particular cases."

The study of American and English authors from a physis standpoint is most interesting. To quote Dr. Reid, Byron's maternal grandmother suffered from melancholia and took her own life. Another relative took poison. His mother was eccentric. His father who was known as "Mad Jack Byron" committed suicide. Charles Lamb's father and sister were insane, his mother suffered from paresis. Dorothy Wordsworth, the sister of the poet, died insane. His daughter, Catherine, suffered from epilepsy and another daughter is said to have been insane at times. DeQuincey's father died of tuberculosis; a sister of hydrocephalus and a son of some obscure brain trouble. The father of Thomas Chatterton was a chronic alcoholic. Pope's mother suffered from senile dementia. Johnson in writing of Pope says: "He inherited headache from his mother and a crooked figure from his father. He was so small of stature that his seat at the table had to be raised to bring him on a level with the others. Dean Swift's uncle died insane. Samuel Johnson's father is described by Murphy as being afflicted with a degree of melancholy little short of madness, violent passions, strong-headed, positive. James Thompson's father suffered from paralysis, his mother from melancholia. Cowper inherited insanity from both sides of his ancestors. Shelly's grandfather suffered from melancholia and his father had tendencies in the same direction. Hartley Coleridge the eldest son of Samuel Taylor Coleridge, bore the hereditary burden of a father addicted to opium and at times insane. He was an eight months' baby and was of abnormally small stature, less than five feet. Sonthey had a maternal uncle who was an idiot. His mother suffered from paralysis in infancy. Sir Walter Scott had a maternal uncle who was insane; his father suffered from organic dementia, his mother from aphasia and post apoplectic dementia; one daughter died of brain fever, another of tuberculosis. Edgar Allen Poe had alcoholic parents and an insane uncle, an imbecile sister and an alcoholic brother."

The author's description of DeQuincey's mental peculiarities is very complete. Quoting from Dr. Eatwell, in his medical review of the life of DeQuincey, it is indicated that he suffered from some nervous trouble during his second or third year. At the age of six he suffered from cataleptic epilepsy. While standing by the casket of his deceased sister

he had a vision in which hallucination of sight and hearing were present. Immediately following this he passed into a depression during which he secluded himself from his family. At twelve he is supposed to have suffered an injury to the head which was followed by mental symptoms. Spencer states that he believes the injury was purely imaginary and gave his opinion that DeQuincey's trouble arose from irritation in his too active and susceptible brain. At sixteen he suffered from a marked depression and wrote a letter to his mother in which he expressed a wish to die. At seventeen the "tide came in" and he suffered from a mild excitement, ran away from school, wandered aimlessly over the hills of Wales, with no object in view except to alleviate his restlessness. He finally wandered to London where the depressed state again ensued. He spent his days idly sitting in the parks and his nights sleeping in hovels. Once he fainted in the street from exhaustion. He entered Oxford at the age of eighteen, soon after admission he again became depressed. It was at this time that he began the use of opium, first taking it for neuralgia. He was a natural morphinist and the drug appears to have had a magical effect upon his disordered mind. "Here he exclaims is a panacea for all human woes. Here is the secret of happiness, about which philosophers have disputed at once discovered." From that time until his death he used the drug at intervals. He remained at Oxford five years, but never received a degree. His examination was progressing nicely, so much so that one member of the faculty said, "You have sent us the cleverest man I ever met." That night DeQuincey disappeared from Oxford and never returned. The stress and strain of the approaching oral examination probably precipitated a depression. At twenty-seven he had an attack of what he describes as nervous horror, which lasted for five months and which disappeared in a night. At twenty-eight he had a depression lasting three months following the death of little Kate Wordsworth. This attack also ended suddenly. The depressions and excitements from which DeQuincey suffered interfered with any continuous effort of any sort. He wrote all the time when he was able, but at thirty he had not published a single line. His literary productions were never finished. Later when he became a regular contributor to various publications he would begin numerous articles which he would never complete.

The remarkable thing about DeQuincey was his insight into his own condition. He writes: "I suffer from the most afflicting derangement of the nervous system which at times makes it difficult for me to write at all."

And again: "A nervous malady of a very

peculiar character which has attacked me intermittently for the last eleven years. My power to make sustained effort dropped in a way I could not control inasmuch that with the parts to be cancelled and with whole days of torpor and pure defect of power to produce anything at all, very often it turned out that all my labors were barely sufficient, (sometimes not sufficient), to meet the current expenses of my residence in London. Sleep and waking became alike in the prevailing sense for sunless gloom and boundless abysses out of which there seemed no hope of rising while space and time alike became boundless, infinite. At length I grew afraid to sleep and I shrank from it as from savage torture. Often I fought with my own drowsiness and kept it aloof by sitting up the whole night and the following day. I sometimes seemed to have lived seventy or a hundred years in one night. In the earlier stage of my malady, the splendor of my dreams was chiefly architectural, and I beheld such pomp of cities and palaces as were never yet beheld by the waking eye, unless in the clouds. But now came a tremendous change. Hitherto the human face mixed often in my dreams, but not despotically nor with any special power of tormenting. Now the appearing of the human face began to unfold itself. The sea seemed to be pale with innumerable faces, wrathful, despairing surged up by thousands, by myriads by generations. No purpose could be answered by my vainly trying to make intelligible for my daughters which I cannot make for myself the indescribable horror that night and day broods over my nervous system."

His "Confessions Of An Opium Eater," were written during a period of excitement without correction or revision. At the time he attempted to revise the work he was seized with depression. He wrote to his publisher as follows:

"A nervous malady which has attacked me intermittently for the last eleven years came on May 1st, almost concurrently with the commencement of this revision and so obstinately has the malady pursued its noiseless and what I may call its subterranean siege that although dedicating myself to this solitary labor, I have spent within six days six calendar months upon the rest of one volume."

Of the excitement of DeQuincey we have little account. Page describes his flight of ideas very aptly:

"His talk is like a stream which runs with rapid change from rocks to roses. It slips from politics to puns. It glides from Mahomet to Moses, beginning with the laws which keep the planets in their courses and ending with some receipt for dressing eels or shoeing horses. His restlessness was great.

He walked a thousand miles in ninety days. He had all the characteristics of a morphinist in his personal appearance which became more and more disordered and in his child-like tendency to keep rubbish hidden in every nook and corner. His library was scattered, his papers in a hopeless state."

DeQuincey's abnormal mental condition has been entirely attributed to the use of opium. As a matter of fact the addiction to opium was the effect rather than the cause of his psychosis. Inasmuch as the latter preceded the former many years. In a letter to a friend DeQuincey says:

"You will naturally ask if there is any key to the original cause. Sincerely I do not believe there is. One inevitable suggestion at first arose to everybody consulted, namely, that it might be some horrid recoil from the long habit of using opium to excess. But this seems improbable for more reasons than one: first, because previously to any considerable use of opium namely in 1812, I suffered from an unaccountable attack of nervous horror, which lasted for five months and went off in one night."

"During his depressions he was able to perform his duties only by the aid of laudanum, a bottle of which set constantly on his desk. He describes its effects as follows:"

"It purifies the moral affection, elevates the imagination and gives a larger scope to it. A power to recreate experiences and fancies of infancy already becoming dim. Opium introduces into the faculties the most exquisite order, regulation and harmony."

How much of DeQuincey's psychosis was colored by opium is impossible to say, but it was possibly responsible to some extent for the hallucinations and delusions so graphically described in his "Confessions of An Opium Eater."

Anemia from *Cercomonas* in the Intestines.—

In Franchini's case the patient had recurring attacks of severe anemia, weakness, abdominal pain and diarrhea during twelve years, with intervals of years of comparative health. Finally a severe attack was traced to the presence of the *Cercomonas* in the intestines; the reds numbered only 500,000 and the hemoglobin was only 17 per cent. when treatment was instituted. The patient rapidly recuperated as the parasites were expelled. In another case a woman had had symptoms of gastric ulcer for years; it finally perforated and in the pus aspirated from the circumscribed peritonitis the *Cercomonas* was found in great numbers. These protozoa had not been responsible probably for the lesion in this case, but their presence had evidently aided in keeping up the chronic irritation.

SELF-MEDICATION.*

By J. H. HOHNSTEDT, Fort Thomas.

Self-medication is an evil practice by a class of people ignorant of the fundamental laws of nature and not capable of comprehending the chemistry of drugs and its relation to the physiological activity of the human body. They consider it time saved and money earned if by some chance they are fortunate, through self-medication to relieve themselves of some uncomfortable symptom. The time-tried home remedies are so cheap that they are usually tried first and often with some gratifying psychological effect. From an economical stand-point many consider the fee of the physician, coupled with the cost of drugs, a burden. Therefore they seek to relieve themselves of their ailments by taking either some of their own prepared decoction, their neighbor's disgusting beverage or one of those widely advertised cure-all patent medicines. They fail to realize that the physician's fee and the cost of a properly prescribed drug would be cheaper than all the money spent for unscientific treatment.

I do not wish to condemn the practice of self-medication when such is done in an emergency pending the arrival of a physician, who probably must travel many miles. Such practice should no more be condemned than to condemn the practice of stopping a hemorrhage by a layman pending the arrival of a physician.

It is for the habitual self-medicators, who are lured by well-worded advertisements, who accept the promises of the nostrum venders, and who in their ignorance may propagate a race inferior in character, that this paper is written. This evil is encouraged by venders of nostrum upon a gullible public. It must be stopped if we wish the coming generations to come into the full vigor of their manhood, thus lessening the admissions to our insane and blind asylums and lessening the criminality defectives.

The history of self-medication dates back to remote ages when our ancestors prepared various decoctions, plasters, ointments, poultices, etc. These formulas were handed down from one generation to another, and prescribed to the sick members of families by their more ignorant folk.

The younger members being taught self-medication would in turn teach their children. They were imbued with a determination to cure all their ills. Those were the days of individual self-medication, the days of darkness, the days when the physician was practically a dispenser of the various nauseating empirical remedies. It was a question as to

whether the home-made remedies or the sickening, disgusting preparation of the physician was best for the patient.

What of to-day, the day of enlightenment, the day when the practice of medicine is based upon a sound rational basis? Is the practice of self-medication still being adhered to? We find among the ignorant that they are using some of the ancient decoctions and preparing smeary, slimy and sticky poultices. And as we go up the scale of human intelligence those nasty preparations have given way to finer and often dangerous preparations. Oleum Ricini and the various salts have taken the place of the ancient cathartics. The druggist carries in his stock more elegantly prepared plasters, ointments and nicely smelling clay poultices. While another having been taught, through literature, that a certain patent medicine is a cure-all, invests his hard-earned money in a worthless, often harmful preparation. The patent medicine venders with their alluring literature, their assurance to the patient that their preparation is the best and only substance to cure him, giving him copies of various endorsements received, followed up by a letter written on a nicely printed letter-head, succeeds in inveigling the unwary victim to enrich the coffers of those human parasites who live and thrive upon the weak. The abominable practice of those patent medicine folks who put on the market and advertise as specifics, pebbles of rank composition, to cure the various chronic diseases as epilepsy, chronic nephritis, diabetes, etc., is a pernicious and inexcusable act. And the quack who will make a diagnosis, for a patient, by mail, and offers to send the patient a trial bottle gratis, performs an unlawful act. He invariably dispenses an alcoholic preparation under the guise of a drug thus escaping the liquor tax. That many have gone to an untimely grave as a result of taking those patent alcoholic preparations in the hope of curing them of tuberculosis is self-evident.

We have with us many mental defectives who have been given various preparations of opium during their childhood by a well-meaning, kind-hearted, yet ignorant mother. Our asylums are filled with pitiable cases of insanity due to self-medication in early childhood or offsprings of parents whose mental faculties have been dulled by the use of opiates, cocaine or alcohol. Our blind asylums contain many unfortunate children, who having had ophthalmia neonatorum, have become a charge on the state and been deprived of that greatest of God-given sense, sight. Yet we find advertisements in the newspapers that gonorrhea can be cured in 24 hours. Is that not one of the most abhorrent methods of self-medication, when some unfortunate accepts

*Read before the Kentucky State Medical Association, Louisville, Tuesday, October 29, 1912.

the promises and follows the directions of those heartless creatures who prey upon the unfortunate? Is it any wonder that so many salpingo-oophorectomies are performed when such people are permitted to foster their wares upon the public?

Some of the most dangerous drugs exploited by the patent medicine man, and I dare say by some unscrupulous pharmacists, are the headache tablets that contain one of the coal-tar derivatives. These tablets are so easy to obtain and so swift in their action that the patient believes he has found a swift and cheap cure. It urges him on to further self-medication. If some new trouble should arise he may go to the druggist, to whom he tells his tale of woe—the druggist apparently listening, will prescribe some patent drug and send him away with the assurance of a cure.

That good neighbor through sympathy for the patient and believing he is doing a kind and brotherly act advises him to take the same medicine that the Doctor prescribed for the neighbor is one of the fruitful sources of self-medication. And the physician who tells his patient to go to the drug store and buy a certain drug urges and teaches the patient that baneful practice. Would he not hesitate to tell him to buy twenty-five cents worth of morphine or cocaine? Yet why should he or does he tell him to purchase a dozen aspirin tablets or ten cents worth of quinine or a pint of elixir I. Q. & S.? The patient employs the physician to cure him and not to teach him self-medication. He is interested in himself and not in the science of the physician and does not care what is prescribed he wants to be cured. Possibly the physician does not realize the harm there may result from such practice. If his purpose be to save money for the patient, then he had better ask the druggist to give medicine without profit. The physician ought to know better and should do better. He should try to eliminate the evil and not encourage it, and if he really has the welfare of his patient at heart he will not do it.

There can be no objections to self-medication when such is done upon a sound rational basis and by those able to make a diagnosis and prescribe intelligently. Yet, how many can do so? To diagnose a case requires the best of medical training and sufficient practice to acquire the skill. It is the hardest part in the practice of medicine and must be done by one who is not biased nor by one whose personal interest is involved. The personal equation hinders the proper diagnosis of a case, and the proper treatment of the same suffers likewise. The physician realizes this when he becomes ill, he knows that auto-diagnosis is impossible, he cannot examine himself

and cannot prescribe for himself intelligently.

In prescribing drugs the physician knows the physiological action and their therapeutic indications and avoids all danger which the self-medicator is liable to aggravate. For instance, he will not give cathartics in volvulus or strangulated hernia, not opiates as an hypnotic to an infant as so many kind-hearted mothers do. Too numerous are the objections to self-medication, therefore let these few suffice, and let us strive to eliminate this evil among a people whose interest is theirs not ours.

This evil can only be eradicated by educating the people and by effective laws. The laity must learn that drugs ought and must be employed scientifically and prescribed intelligently by those able to make a proper diagnosis. They must be taught the harm that may result to themselves and their offspring if self-medication be persisted in.

If the mother were told the harmful effects and taught the physiological action of paregoric she would cease its use and warn others. If she were told that most of the soothing syrups contain opium or one of its derivatives and that it hides and obscures the cause of the baby's ailment she would discontinue using it so indiscriminately for every irritable symptom of the baby. The asthmatic and the sufferers of hay fever must be warned about cocaine, the principal ingredient of most of the patent asthmatic and hay fever remedies. The tubercular patient, in his anxiety to be cured, easily becomes a victim of patent medicine. He is easily influenced by the promises of the quack and easily succumbs to their ensnaring grasp. Many sufferers of malignant growths, epilepsy, diabetes, rheumatism or other curable and incurable diseases become a prey of the quack and nostrum vender.

The Journal of the A. M. A. and Collier's Weekly have so bravely and fearlessly exposed the fraudulent methods of those human parasites, that it behooves the physician to help spread that propaganda they have so unselfishly undertaken, thus aiding them in destroying the evil and saving life. The harmful effects of self-medication, especially the taking of patent drugs, should be prominently brought to the attention of the laity. This can be done by public lecture or private conversation with our patients, friends or acquaintances. Where neither are practicable, then literature, which is easy to obtain and so cheap, can be distributed among that class of people where it would do the most good.

Another way to curb the insatiable greed of the nostrum venders is effective laws. Each

state ought to have laws on their statute books prohibiting the sale of dangerous drugs by anyone not qualified to so prescribe. Every bottle or package containing patent medicine should state on its label the ingredient therein. No untruthful statement pertaining to its therapeutic indication permitted. The National pure food and drugs act has recently been amended whereby the deception as to the therapeutic indication of drugs so persistently and indiscriminately practiced by the nostrum venders can be curbed. It ought also absolutely prohibit the transportation of habit-forming drugs from one state to another, except within the legitimate channels of trade or by a qualified physician. Then the selling of morphine to cure the morphine habit, or cocaine to cure hay-fever would be stopped.

I am aware of the fact that many people look with suspicion at the motive of the medical profession when they strive to eradicate an evil. Let that not deter us from doing that work which is for the good of humanity and which each of us ought to consider a duty. It is by persistently striving to attain that which is good that we accomplish anything. Therefore let us use every legitimate means possible of eradicating this evil, especially among those who are ignorant of the ingredients they use.

When the time comes that the laity awakens to a realization of the harmful effects in the indiscriminate use of self-prescribed remedies and accept that which is scientifically indicated, after an intelligent diagnosis has been made, then we may look forward to a better race, a race that will gradually eliminate all preventable diseases. They will learn that hygienic conditions and a properly prescribed remedy is essential to the preservation of health and the cure of diseases. The physical and mental conditions of their offsprings will be so nearly balanced that the world will say, "he is a man." The admissions to our insane and blind asylums will gradually decrease in number, our criminally defective become lessened, thus permitting our asylums to become hospitals and homes for the sick and aged, and life be one sweet round of earthly existence.

This is a consummation devoutly to be wished.

BOOK REVIEWS

A Manual of Personal Hygiene.—Proper Living upon a Physiologic Basis. By Eminent Specialists. Edited by Walter L. Pyle, M. D., Assistant Surgeon to the Wills Eye Hospital, Philadelphia. Fifth Edition, Revised and Enlarged. 12mo of 516 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1912. Cloth, \$1.50 net.

The Fifth Edition of this successful book shows on every page evidences of the most conscientious revision. Dr. Pyle has gathered around him as collaborators men who know their subjects, and better still, they know how to impart their knowledge. We emphasize this fact particularly, because Pyle's work is intended for the general public.

By far the most important addition to this edition is the chapter on Food Adulteration and Deterioration by that eminent benefactor, Harvey W. Wiley. This chapter alone is worth the price of the book to every mother who naturally is interested in the health of her family.

The book in every way is excellent, not the least feature by any means being the chapters on Home Gymnastics and Domestic Hygiene. We strongly urge that every doctor recommend this book to his patients. It should be on the library table of every home.

A Text-Book on the Practice of Gynecology.—For Practitioners and Students. By W. Easterly Ashton, M. D., LL. D., Professor of Gynecology in the Medico-Chirurgical College of Philadelphia. Fifth Edition, Thoroughly Revised. Octavo of 1100 pages, with 1050 original line drawings. Philadelphia and London: W. B. Saunders Company, 1912. Cloth, \$6.50 net; Half Morocco, \$8.00 net.

The writer has always held that Dr. Ashton's Gynecology is the most practical all-around work on this subject ever published. Five editions and seven reprints, (a total of twelve printings) in seven years, certainly shows that he is not alone in his opinion. Dr. Ashton set out to write a book that took nothing for granted—and he wrote it. Furthermore he illustrated it with over 1000 line drawings that were new and that show just what they should show, and nothing more. This made for clearness, and these two features insure the success.

In revising his work, Dr. Ashton has not lost sight of his original plan. He has added all the new advances in the same detailed way. He has added much new matter on the blood in relation to surgery; on the DeKesting-Hart method of thermoradiotherapy and the fulguration treatment for Cancer. He has added the recent advances in diagnosis and treatment of syphilis with special reference to excision of the primary lesion, and to the use of salvarsan. The subject

of gonorrhoea has been brought right down to date, including the use of stock vaccines. The hormone and its bearing upon diseases of women has been fully presented. The Fowler-Murphy method of treating suppurative peritonitis, the use of iodine as an antiseptic and in sterilization of the skin for operation has been given the places their usefulness undoubtedly demand.

Many changes have been made in the operative technic and new operations substituted for those more or less obsolete. Probably the most important additions, in this part of the work is the inclusion of Baldy's round ligament operation for retro-displacement, Ward's method of operating for inaccessible vesicovaginal fistulas has been fully described. Tuttle's proctoscope and sigmoidoscope have been substituted for speculums with reflected light. The operation of appendectomy has been entirely rewritten and the author's method of securing the colon with Mohnyhan's clamps substituted for the former technic. These are only a few of the great number of important changes throughout the book. Ashton at once jumped into the fore-rank of books covering this field. This new edition will undoubtedly strengthen its position. As I said above, I think it is without question the best book on gynecology before the profession today.

Diseases of the Stomach, Intestines, and Pancreas.—By Robert Coleman Kemp, M. D. Professor of Gastro-Intestinal Diseases, New York School of Clinical Medicine. Second edition, revised and enlarged. Octavo of 1021 pages, with 388 illustrations. Philadelphia and London: W. B. Saunders Company, 1912. Cloth, \$6.50 net; Half Morocco, \$8.00 net.

The publishers call this new edition of Kemp a revision. They would have been more correct had they called it a new work, for that is what this new edition really is. Perhaps the most noteworthy additions are an extended chapter on the pancreas covering 100 pages, and one on colon bacilli infections. These are extremely complete and strikingly expressive of the newest thought.

A chapter that has been rewritten is that on the Esophagus and its diseases. Here the reviewer finds all the recent work in this field presented in a way most available for every day practice.

The same is true of the section on Gastric Cancer. In fact, there is nothing of real value omitted in any of the three fields covered. Diagnosis and Treatment are particularly full throughout the book and Dr. Kemp has introduced a number of valuable methods not to be found in other works. In fact, he has introduced some methods that are new to this country.

These three fields are always a sort of trouble to the general practitioner, but with this volume he

will find the rough ways made smooth and the crooked paths made straight.

Text Book of General and Special Pathology. By Henry T. Brooks, M. D., former professor of Pathology at the New York Post-Graduate Medical School and Hospital; consulting Pathologist, N. Y. Hospitals; Bacteriologist to St. Mark's Hospital, New York; etc., illustrated with 500 half tone and other engravings (110 in colors). to Beth-Israel, New York City, and New Roch-also 15 full page plates in colors, containing 40 figures. Published by F. A. Davis Company, Philadelphia. This book meets with the requirements in a very satisfactory way to those who desire standard references for General and Special Pathology. The illustrations are good, texts clear and the scope of the work sufficient for the general practitioner.

International Clinics, Volume 3, 22nd Series.—Some splendid articles, under the department of Diagnosis and Treatment, are to be found in this volume. The diagnosis for treatment of locomotor ataxia, by Maloney; the treatment of chronic Endocarditis, by Williams, are two of special value; spontaneous gangrene is treated by Roussel, Tuberculosis of the Genito-Urinary Organs, by Bevan, are two of the best under the department of medicine. The article on Flat-foot is worth the price of the volume. Published by J. B. Lippincott Company, Philadelphia. Price \$2.00.

Muscle Spasm and Degeneration in Intra-thoracic Inflammations.—By Francis Pottenger, A. M. M. D., LL. D., Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California. Sixteen illustrations. Price \$2.00. C. V. Mosby Company, Publishers, St. Louis, Missouri.

The material combined in this monograph is based upon several thousand physical examinations and the review of this work will add much to the physician's knowledge in making an earlier diagnosis of the tuberculosis.

The change on the part of the muscle and light touch palpation, as outlined in these pages, emphasizes inspection and palpation which have been heretofore neglected in the diagnosis of intrathoracic diseases. If the examiner will apply the principles so thoroughly described by the author, far more knowledge can be obtained than by discussion.
